Lead has many different uses. It is used in the production of batteries, ammunition, metal products (solder and pipes), and devices to shield X-rays. Because of health concerns, lead from paints and ceramic products, caulking, and pipe solder has been dramatically reduced in recent years. The use of lead as an additive to gasoline was banned in 1996 in the United States.

What happens to lead when it enters the environment?

- Lead itself does not break down, but lead compounds are changed by sunlight, air, and water.
- When lead is released to the air, it may travel long distances before settling to the ground.
- Once lead falls onto soil, it usually sticks to soil particles.
- Movement of lead from soil into groundwater will depend on the type of lead compound and the characteristics of the soil.

How might I be exposed to lead?

- Eating food or drinking water that contains lead. Water pipes in some older homes may contain lead solder. Lead can leach out into the water.

- Spending time in areas where lead-based paints have been used and are deteriorating. Deteriorating lead paint can contribute to lead dust.

- Working in a job where lead is used or engaging in certain hobbies in which lead is used, such as making stained glass.

- Using health-care products or folk remedies that contain lead.

How can lead affect my health?

The effects of lead are the same whether it enters the body through breathing or swallowing. Lead can affect almost every organ and system in your body. The main target for lead toxicity is the nervous system, both in adults and children. Long-term exposure of adults can result in decreased performance in some tests that measure functions of the nervous system. It may also cause weakness in fingers, wrists, or ankles. Lead exposure also causes small increases in blood pressure, particularly in middle-aged and older people and can cause anemia. Exposure to high lead levels can severely damage the brain and kidneys in adults or children and ultimately cause death. In pregnant women, high levels of exposure to lead may cause miscarriage. High-level exposure in men can damage the organs responsible for sperm production.

How likely is lead to cause cancer?

We have no conclusive proof that lead causes cancer in humans. Kidney tumors have developed in rats and mice that had been given large doses of some kind of lead compounds. The Department of Health and Human Services

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

(DHHS) has determined that lead and lead compounds are reasonably anticipated to be human carcinogens and the EPA has determined that lead is a probable human carcinogen. The International Agency for Research on Cancer (IARC) has determined that inorganic lead is probably carcinogenic to humans and that there is insufficient information to determine whether organic lead compounds will cause cancer in humans.

How can lead affect children?

Small children can be exposed by eating lead-based paint chips, chewing on objects painted with lead-based paint, or swallowing house dust or soil that contains lead.

Children are more vulnerable to lead poisoning than adults. A child who swallows large amounts of lead may develop blood anemia, severe stomachache, muscle weakness, and brain damage. If a child swallows smaller amounts of lead, much less severe effects on blood and brain function may occur. Even at much lower levels of exposure, lead can affect a child's mental and physical growth.

Exposure to lead is more dangerous for young and unborn children. Unborn children can be exposed to lead through their mothers. Harmful effects include premature births, smaller babies, decreased mental ability in the infant, learning difficulties, and reduced growth in young children. These effects are more common if the mother or baby was exposed to high levels of lead. Some of these effects may persist beyond childhood.

How can families reduce the risks of exposure to lead?

- Avoid exposure to sources of lead.
- Do not allow children to chew on mouth surfaces that may have been painted with lead-based paint.
- If you have a water lead problem, run or flush water that has been standing overnight before drinking or cooking with it.
- Some types of paints and pigments that are used as make-up or hair coloring contain lead. Keep these kinds of products away from children
- If your home contains lead-based paint or you live in an area contaminated with lead, wash children's hands and faces

often to remove lead dusts and soil, and regularly clean the house of dust and tracked in soil.

Is there a medical test to determine whether I've been exposed to lead?

A blood test is available to measure the amount of lead in your blood and to estimate the amount of your recent exposure to lead. Blood tests are commonly used to screen children for lead poisoning. Lead in teeth or bones can be measured by X-ray techniques, but these methods are not widely available. Exposure to lead also can be evaluated by measuring erythrocyte protoporphyrin (EP) in blood samples. EP is a part of red blood cells known to increase when the amount of lead in the blood is high. However, the EP level is not sensitive enough to identify children with elevated blood lead levels below about 25 micrograms per deciliter ($\mu\text{g}/\text{dL}$). These tests usually require special analytical equipment that is not available in a doctor's office. However, your doctor can draw blood samples and send them to appropriate laboratories for analysis.

Has the federal government made recommendations to protect human health?

The Centers for Disease Control and Prevention (CDC) recommends that states test children at ages 1 and 2 years. Children should be tested at ages 3–6 years if they have never been tested for lead, if they receive services from public assistance programs for the poor such as Medicaid or the Supplemental Food Program for Women, Infants, and Children, if they live in a building or frequently visit a house built before 1950; if they visit a home (house or apartment) built before 1978 that has been recently remodeled; and/or if they have a brother, sister, or playmate who has had lead poisoning. CDC considers a blood lead level of 10 $\mu\text{g}/\text{dL}$ to be a level of concern for children.

EPA limits lead in drinking water to 15 μg per liter.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology and Environmental Medicine, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-800-232-4636, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because these substances may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene happens mostly from breathing air contaminated from the burning of wood, tobacco, or fossil fuels, industrial discharges, or moth repellents. Exposure to large amounts of naphthalene may damage or destroy some of your red blood cells. Naphthalene has caused cancer in animals. Naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene have been found in at least 687, 36, and 412, respectively, of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What are naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

Naphthalene is a white solid that evaporates easily. Fuels such as petroleum and coal contain naphthalene. It is also called white tar, and tar camphor, and has been used in mothballs and moth flakes. Burning tobacco or wood produces naphthalene. It has a strong, but not unpleasant smell. The major commercial use of naphthalene is in the manufacture of polyvinyl chloride (PVC) plastics. Its major consumer use is in moth repellents and toilet deodorant blocks.

1-Methylnaphthalene and 2-methylnaphthalene are naphthalene-related compounds. 1-Methylnaphthalene is a clear liquid and 2-methylnaphthalene is a solid; both can be smelled in air and in water at very low concentrations.

1-Methylnaphthalene and 2-methylnaphthalene are used to make other chemicals such as dyes and resins. 2-Methylnaphthalene is also used to make vitamin K.

What happens to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene when they enter the environment?

- Naphthalene enters the environment from industrial and domestic sources, and from accidental spills.
- Naphthalene can dissolve in water to a limited degree and may be present in drinking water from wells close to hazardous waste sites and landfills.
- Naphthalene can become weakly attached to soil or pass through soil into underground water.
- In air, moisture and sunlight break it down within 1 day. In water, bacteria break it down or it evaporates into the air.
- Naphthalene does not accumulate in the flesh of animals or fish that you might eat.

1-Methylnaphthalene and 2-methylnaphthalene are expected to act like naphthalene in air, water, or soil because they have similar chemical and physical properties.

How might I be exposed to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

- Breathing low levels in outdoor air.
- Breathing air contaminated from industrial discharges or smoke from burning wood, tobacco, or fossil fuels.
- Using or making moth repellents, coal tar products, dyes or inks could expose you to these chemicals in the air.
- Drinking water from contaminated wells.
- Touching fabrics that are treated with moth repellents containing naphthalene.
- Exposure to naphthalene, 1-methylnaphthalene and 2-methylnaphthalene from eating foods or drinking beverages is unlikely.

How can naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene affect my health?

Exposure to large amounts of naphthalene may damage or destroy some of your red blood cells. This could cause you to have too few red blood cells until your body replaces the destroyed cells. This condition is called hemolytic anemia. Some symptoms of hemolytic anemia are fatigue, lack of appetite, restlessness, and pale skin. Exposure to large amounts of naphthalene may also cause nausea, vomiting, diarrhea, blood in the urine, and a yellow color to the skin. Animals sometimes develop cloudiness in their eyes after swallowing high amounts of naphthalene. It is not clear whether this also develops in people. Rats and mice that breathed naphthalene vapors daily for a lifetime developed irritation and inflammation of their nose and lungs. It is unclear if naphthalene

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

causes reproductive effects in animals; most evidence says it does not.

There are no studies of humans exposed to 1-methylnaphthalene or 2-methylnaphthalene.

Mice fed food containing 1-methylnaphthalene and 2-methylnaphthalene for most of their lives had part of their lungs filled with an abnormal material.

How likely are naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene to cause cancer?

There is no direct evidence in humans that naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene cause cancer.

However, cancer from naphthalene exposure has been seen in animal studies. Some female mice that breathed naphthalene vapors daily for a lifetime developed lung tumors. Some male and female rats exposed to naphthalene in a similar manner also developed nose tumors.

Based on the results from animal studies, the Department of Health and Human Services (DHHS) concluded that naphthalene is reasonably anticipated to be a human carcinogen. The International Agency for Research on Cancer (IARC) concluded that naphthalene is possibly carcinogenic to humans. The EPA determined that naphthalene is a possible human carcinogen (Group C) and that the data are inadequate to assess the human carcinogenic potential of 2-methylnaphthalene.

How can naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene affect children?

Hospitals have reported many cases of hemolytic anemia in children, including newborns and infants, who either ate naphthalene mothballs or deodorants cakes or who were in close contact with clothing or blankets stored in naphthalene mothballs. Naphthalene can move from a pregnant woman's blood to the unborn baby's blood. Naphthalene has been detected in some samples of breast milk from the general U.S. population, but not at levels that are expected to be of concern.

There is no information on whether naphthalene has affected development in humans. No developmental abnormalities were observed in the offspring from rats, mice, and rabbits fed naphthalene during pregnancy.

We do not have any information on possible health effects of 1-methylnaphthalene or 2-methylnaphthalene on children.

How can families reduce the risks of exposure to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

Families can reduce the risks of exposure to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene by avoiding smoking tobacco, generating smoke during cooking, or using

fireplaces or heating appliances in their homes.

If families use naphthalene-containing moth repellents, the material should be enclosed in containers that prevent vapors from escaping, and kept out of the reach from children.

Blankets and clothing stored with naphthalene moth repellents should be aired outdoors to remove naphthalene odors and washed before they are used.

Families should inform themselves of the contents of air deodorizers that are used in their homes and refrain from using deodorizers with naphthalene.

Is there a medical test to determine whether I've been exposed to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

Tests are available that measure levels of these chemicals and their breakdown products in samples of urine, feces, blood, maternal milk, or body fat. These tests are not routinely available in a doctor's office because they require special equipment, but samples can be sent to special testing laboratories. These tests cannot determine exactly how much naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene you were exposed to or predict whether harmful effects will occur. If the samples are collected within a day or two of exposure, then the tests can show if you were exposed to a large or small amount of naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene.

Has the federal government made recommendations to protect human health?

The EPA recommends that children not drink water with over 0.5 parts per million (0.5 ppm) naphthalene for more than 10 days or over 0.4 ppm for any longer than 7 years. Adults should not drink water with more than 1 ppm for more than 7 years. For water consumed over a lifetime (70 years), the EPA suggests that it contain no more than 0.1 ppm naphthalene.

The Occupational Safety and Health Administration (OSHA) set a limit of 10 ppm for the level of naphthalene in workplace air during an 8-hour workday, 40-hour workweek. The National Institute for Occupational Safety and Health (NIOSH) considers more than 500 ppm of naphthalene in air to be immediately dangerous to life or health. This is the exposure level of a chemical that is likely to impair a worker's ability to leave a contaminate area and therefore, results in permanent health problems or death.

This fact sheet answers the most frequently asked health questions (FAQs) about nickel. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Nickel is a naturally occurring element. Pure nickel is a hard, silvery-white metal used to make stainless steel and other metal alloys. Skin effects are the most common effects in people who are sensitive to nickel. Workers who breathed very large amounts of nickel compounds developed chronic bronchitis and lung and nasal sinus cancers. Nickel has been found in at least 882 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is nickel?

Nickel is a very abundant natural element. Pure nickel is a hard, silvery-white metal. Nickel can be combined with other metals, such as iron, copper, chromium, and zinc, to form alloys. These alloys are used to make coins, jewelry, and items such as valves and heat exchangers. Most nickel is used to make stainless steel.

Nickel can combine with other elements such as chlorine, sulfur, and oxygen to form nickel compounds. Many nickel compounds dissolve fairly easy in water and have a green color. Nickel compounds are used for nickel plating, to color ceramics, to make some batteries, and as substances known as catalysts that increase the rate of chemical reactions. Nickel is found in all soil and is emitted from volcanoes. Nickel is also found in meteorites and on the ocean floor. Nickel and its compounds have no characteristic odor or taste.

What happens to nickel when it enters the environment?

- Nickel is released into the atmosphere by industries that make or use nickel, nickel alloys, or nickel compounds. It is also released into the atmosphere by oil-burning power plants, coal-burning power plants, and trash incinerators.
- In the air, it attaches to small particles of dust that settle to the ground or are taken out of the air in rain or snow; this usually takes many days.

- Nickel released in industrial waste water ends up in soil or sediment where it strongly attaches to particles containing iron or manganese.
- Nickel does not appear to accumulate in fish or in other animals used as food.

How might I be exposed to nickel?

- By eating food containing nickel, which is the major source of exposure for most people.
- By skin contact with soil, bath or shower water, or metals containing nickel, as well as by handling coins or touching jewelry containing nickel.
- By drinking water that contains small amounts of nickel.
- By breathing air or smoking tobacco containing nickel.
- Higher exposure may occur if you work in industries that process or use nickel.

How can nickel affect my health?

The most common harmful health effect of nickel in humans is an allergic reaction. Approximately 10-20% of the population is sensitive to nickel. People can become sensitive to nickel when jewelry or other things containing it are in direct contact with the skin for a long time. Once a person is sensitized to nickel, further contact with the metal may produce a reaction. The most common reaction is a skin rash at the site of contact. The skin rash may also

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

occur at a site away from the site of contact. Less frequently, some people who are sensitive to nickel have asthma attacks following exposure to nickel. Some sensitized people react when they consume food or water containing nickel or breathe dust containing it.

People working in nickel refineries or nickel-processing plants have experienced chronic bronchitis and reduced lung function. These persons breathed amounts of nickel much higher than levels found normally in the environment.

Workers who drank water containing high amounts of nickel had stomach ache and suffered adverse effects to their blood and kidneys.

Damage to the lung and nasal cavity has been observed in rats and mice breathing nickel compounds. Eating or drinking large amounts of nickel has caused lung disease in dogs and rats and has affected the stomach, blood, liver, kidneys, and immune system in rats and mice, as well as their reproduction and development.

How likely is nickel to cause cancer?

Cancers of the lung and nasal sinus have resulted when workers breathed dust containing high levels of nickel compounds while working in nickel refineries or nickel processing plants. The Department of Health and Human Services (DHHS) has determined that nickel metal may reasonably be anticipated to be a carcinogen and that nickel compounds are known human carcinogens. The International Agency for Research on Cancer (IARC) has determined that some nickel compounds are carcinogenic to humans and that metallic nickel may possibly be carcinogenic to humans. The EPA has determined that nickel refinery dust and nickel subsulfide are human carcinogens.

How can nickel affect children?

It is likely that the health effects seen in children exposed to nickel will be similar to those seen in adults. We do not know whether children differ from adults in their susceptibility to nickel. Human studies that examined whether nickel can harm the fetus are inconclusive. Animal studies have found increases in newborn deaths and

decreased newborn weight after ingesting very high amounts of nickel. Nickel can be transferred from the mother to an infant in breast milk and can cross the placenta.

How can families reduce the risks of exposure to nickel?

- Avoiding jewelry containing nickel will eliminate risks of exposure to this source of the metal.
- Exposures of the general population from other sources, such as foods and drinking water, are almost always too low to be of concern.

Is there a medical test to determine whether I've been exposed to nickel?

There are tests available to measure nickel in your blood, feces, and urine. More nickel was measured in the urine of workers who were exposed to nickel compounds that dissolve easily in water than in the urine of workers exposed to nickel compounds that are hard to dissolve. This means that it is easier to tell if you have been exposed to soluble nickel compounds than less-soluble compounds. The nickel measurements do not accurately predict potential health effects from exposure to nickel.

Has the federal government made recommendations to protect human health?

The EPA recommends that drinking water should contain no more than 0.1 milligrams of nickel per liter of water (0.1 mg/L). To protect workers, the Occupational Safety and Health Administration (OSHA) has set a limit of 1 mg of nickel per cubic meter of air (1 mg/m³) for metallic nickel and nickel compounds in workplace air during an 8-hour workday, 40-hour workweek.

References

Agency for Toxic Substances and Disease Registry (ATSDR). 2005. Toxicological Profile for Nickel (Update). Atlanta, GA: U.S. Department of Public Health and Human Services, Public Health Service.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about polycyclic aromatic hydrocarbons (PAHs). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to polycyclic aromatic hydrocarbons usually occurs by breathing air contaminated by wild fires or coal tar, or by eating foods that have been grilled. PAHs have been found in at least 600 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What are polycyclic aromatic hydrocarbons?

(Pronounced pŏl'ī-sī'klīk ār'ə-măt'īk hī'drə-kar'bənz)

Polycyclic aromatic hydrocarbons (PAHs) are a group of over 100 different chemicals that are formed during the incomplete burning of coal, oil and gas, garbage, or other organic substances like tobacco or charbroiled meat. PAHs are usually found as a mixture containing two or more of these compounds, such as soot.

Some PAHs are manufactured. These pure PAHs usually exist as colorless, white, or pale yellow-green solids. PAHs are found in coal tar, crude oil, creosote, and roofing tar, but a few are used in medicines or to make dyes, plastics, and pesticides.

What happens to PAHs when they enter the environment?

- PAHs enter the air mostly as releases from volcanoes, forest fires, burning coal, and automobile exhaust.
- PAHs can occur in air attached to dust particles.
- Some PAH particles can readily evaporate into the air from soil or surface waters.
- PAHs can break down by reacting with sunlight and other chemicals in the air, over a period of days to weeks.

- PAHs enter water through discharges from industrial and wastewater treatment plants.
- Most PAHs do not dissolve easily in water. They stick to solid particles and settle to the bottoms of lakes or rivers.
- Microorganisms can break down PAHs in soil or water after a period of weeks to months.
- In soils, PAHs are most likely to stick tightly to particles; certain PAHs move through soil to contaminate underground water.
- PAH contents of plants and animals may be much higher than PAH contents of soil or water in which they live.

How might I be exposed to PAHs?

- Breathing air containing PAHs in the workplace of coking, coal-tar, and asphalt production plants; smoke-houses; and municipal trash incineration facilities.
- Breathing air containing PAHs from cigarette smoke, wood smoke, vehicle exhausts, asphalt roads, or agricultural burn smoke.
- Coming in contact with air, water, or soil near hazardous waste sites.
- Eating grilled or charred meats; contaminated cereals, flour, bread, vegetables, fruits, meats; and processed or pickled foods.
- Drinking contaminated water or cow's milk.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

- ❑ Nursing infants of mothers living near hazardous waste sites may be exposed to PAHs through their mother's milk.

How can PAHs affect my health?

Mice that were fed high levels of one PAH during pregnancy had difficulty reproducing and so did their offspring. These offspring also had higher rates of birth defects and lower body weights. It is not known whether these effects occur in people.

Animal studies have also shown that PAHs can cause harmful effects on the skin, body fluids, and ability to fight disease after both short- and long-term exposure. But these effects have not been seen in people.

How likely are PAHs to cause cancer?

The Department of Health and Human Services (DHHS) has determined that some PAHs may reasonably be expected to be carcinogens.

Some people who have breathed or touched mixtures of PAHs and other chemicals for long periods of time have developed cancer. Some PAHs have caused cancer in laboratory animals when they breathed air containing them (lung cancer), ingested them in food (stomach cancer), or had them applied to their skin (skin cancer).

Is there a medical test to show whether I've been exposed to PAHs?

In the body, PAHs are changed into chemicals that can attach to substances within the body. There are special tests that can detect PAHs attached to these substances in body tissues or blood. However, these tests cannot tell whether any

health effects will occur or find out the extent or source of your exposure to the PAHs. The tests aren't usually available in your doctor's office because special equipment is needed to conduct them.

Has the federal government made recommendations to protect human health?

The Occupational Safety and Health Administration (OSHA) has set a limit of 0.2 milligrams of PAHs per cubic meter of air (0.2 mg/m^3). The OSHA Permissible Exposure Limit (PEL) for mineral oil mist that contains PAHs is 5 mg/m^3 averaged over an 8-hour exposure period.

The National Institute for Occupational Safety and Health (NIOSH) recommends that the average workplace air levels for coal tar products not exceed 0.1 mg/m^3 for a 10-hour workday, within a 40-hour workweek. There are other limits for workplace exposure for things that contain PAHs, such as coal, coal tar, and mineral oil.

Glossary

Carcinogen: A substance that can cause cancer.

Ingest: Take food or drink into your body.

ATTACHMENT E-2

PHASE I SCREENING RISK EVALUATION FOR PARCO EVA RESIDENCES

**This page has been left blank intentionally
to allow for double-sided printing.**

NAPLES Public Health Evaluation

U.S. Navy, Naples Housing Office Premise ID: Parco Eva

Dear Parco Eva Resident:

SUBJECT: Phase I Screening Risk Evaluation for Parco Eva Residences

The Navy Public Health Evaluation Team has completed a Screening Risk Evaluation (SRE) of soil, soil gas, and tap water samples that were collected at Parco Eva residences and common areas from 07/04/2008 to 07/14/2008 (See Figure 1). The purpose of the SRE is to evaluate the potential human health risks to Navy personnel and their families residing in the Naples area as a result of public health concerns that could be related to improper refuse disposal (including open burning) and hazardous waste disposal practices. This memo summarizes the results of the investigation that was performed at Parco Eva residences and common areas. These sampling results were compared to U.S. Environmental Protection Agency (USEPA) health standards and of the twelve locations sampled in the Parco, all twelve have been assessed to be Acceptable. Ambient air samples were also collected at Parco Eva as part of a year-long air study and the results will be evaluated after all of the data have been collected and analyzed.

SCREENING RISK EVALUATION RESULTS

The environmental sampling results for soil, soil gas, and tap water were compared to risk-based regional screening levels (RSLs) and drinking water standards (maximum contaminant levels [MCLs]) to evaluate potential risks to human health. These levels are considered by the USEPA to be protective of human health. Concentrations of chemicals in soil, soil gas, and tap water that exceed these levels may be of concern. Please see Attachment A for further discussion of the SRE approach.

These sampling results are being used as the basis for making recommendations for your residence. They will also be used as part of the overall effort in evaluating potential risks in the Naples area. The two potential outcomes of the SRE are that risks at your residence were: 1) Acceptable or 2) Unacceptable. Please see Attachment B for further discussion of these risk categories. This determination is based on a number of factors and assumes that an individual lives at the residence for 30-years, which is typically used by the USEPA to evaluate residential locations. Your actual risk may be significantly less than the risks presented in this memo. For example, if you live at this location for only three years and do not drink the tap water, then your risks will be significantly less than those presented in this memo.

Finally, risks presented in this SRE are based on a single sampling event. A single sample only provides a "snapshot" of concentrations that are present in soil, soil gas, and tap water. One sample may or may not be representative of the soil, soil gas, and tap water concentrations present each location. Please see Attachment C for the sampling results for all Parco Eva locations.

SUBJECT: Phase I Screening Risk Evaluation for Parco Eva Residences

Typically, in SRE reports, total risks are determined by calculating the potential risk for all of the various ways one might be exposed to contaminants, which are referred to as exposure pathways such as ingestion, inhalation, dermal contact, et cetera. For Naples, Navy leadership has implemented a Bottled Water Advisory and is requiring landlords to provide a water service from Navy-approved sources to eliminate the tap water ingestion exposure pathway. Therefore, we are calculating the risk two ways, assuming exposure via the ingestion pathway, and assuming no exposure via the ingestion pathway. Both of these risk determinations are described below and a table presenting the comparison of the environmental sampling results collected at Parco Eva and applicable screening concentrations is presented in Attachment D.

Risks Calculated for Individual Parco Eva Residences

Risks Calculated Assuming that Tap Water IS Used for Drinking, Cooking, Brushing Teeth and Making Ice

If the tap water at Parco Eva is used for drinking, cooking, brushing teeth, and making ice (in addition to other household uses), then based on USEPA RSLs and MCLs, the risks at nine out of ten residences are Acceptable and one is Unacceptable (i.e., EV11) because the total cancer risk exceedance factor (summed based on exposure to soil, soil gas, and tap water) was greater than 10. Of the nearly 220 chemicals that were tested in soil and tap water and the approximately 40 that were tested for in soil gas, two were detected at levels of potential concern¹.

Risks Calculated Assuming that Tap Water IS NOT Used for Drinking, Cooking, Brushing Teeth and Making Ice

The Navy has determined that the tap water in Naples should not be used for drinking, cooking, brushing teeth, or making ice. Therefore, if the tap water at Parco Eva is not used for drinking, cooking, brushing teeth, and making ice (i.e., tap water is only used for other household uses such as showering or washing clothes), then based on USEPA RSLs and MCLs, the risks at all ten residences are Acceptable. Of the nearly 220 chemicals that were tested in soil and tap water and approximately 40 that were tested for in soil gas, one was detected at a level of potential concern¹.

Summary of Chemical-Specific Results

In soil gas, tetrachloroethene exceeded its RSL at locations EV04 and EV11. In tap water, total dioxin/furans exceeded its RSL at locations EV09 and EV12. Please see Table 1 for a summary of Parco Eva residence risks by location.

- 1) Tetrachloroethene is a solvent commonly used to dry clean clothes and the inhalation RSL exceedance cannot be mitigated by using bottled water.
- 2) The total dioxin/furans ingestion RSL exceedances are mitigated by the use of bottled water. Dioxins/Furans are a group of chemicals that are called chlorinated dibenzo-p-

¹ This excludes naturally-occurring chemicals, such as arsenic.

SUBJECT: Phase I Screening Risk Evaluation for Parco Eva Residences

dioxins and dibenzo-p-furans. These chemicals can be produced during incomplete burning of wood or materials such as garbage.

For more information on these chemicals, please see Attachment E.

Risks Calculated for Parco Eva Common Areas

Two soil samples (locations EV01 and EV02) were collected from a common area located on the east-side of the parco (see Figure 1). These samples were also compared to USEPA RSLs to evaluate potential risks to human health and the risks at both locations have been assessed to be Acceptable. Please see Table 1 for a summary of Parco Eva residence risks by location.

None of the nearly 220 chemicals that were tested in soil were detected at levels of potential concern in the common areas. However, the concentrations of naturally-occurring arsenic in soil were above its RSL.

It should be noted that the concentrations of naturally-occurring arsenic in soil and tap water were above RSLs at all Parco Eva residences and the concentration of naturally-occurring nickel in tap water at location EV07 was above its RSL.

- 1) Arsenic in soil and tap water is often associated with volcanic activity. This is similar to areas in the United States (e.g., Puget Sound, Washington).
- 2) Nickel is a very abundant natural element that can be combined with other metals, such as iron, copper, chromium, and zinc, to form alloys, most commonly stainless steel. These alloys are also used to make coins, jewelry, and items such as valves and heat exchangers.

USEPA risk assessors also consider background concentrations of naturally-occurring metals (identified as Inorganics in Attachment D), such as arsenic and nickel, when evaluating risks. The concentrations of these naturally-occurring substances found at your residence were not included in risk-management decisions. The concentrations of metals in soil at your residence were similar to background concentrations found in the Naples area. The concentrations of arsenic and nickel in tap water were below the MCL for all Parco Eva residences. For more information on arsenic and nickel, please see Attachment E.

The risk-management decision (i.e., Acceptable or Unacceptable) presented in this memo is based on the Incremental Risk (i.e., the risks not including natural background). See the footnotes in Attachment D for more information.

SUBJECT: Phase I Screening Risk Evaluation for Parco Eva Residences

Actions that the Navy is Taking Based on the Sampling Results

Based on the results of the environmental sampling performed at Parco Eva, the following actions will be implemented:

- a) Bottled water will continue to be provided by the Navy until such time as the Navy's lease for this property is modified to require the landlord to provide containerized water.
- b) The bottled water advisory issued in 2008 is still in place.
- c) The Navy will ensure that any water holding tanks and associated plumbing are regularly cleaned and disinfected.
- d) Italian authorities have been and will continue to be notified of the results of the environmental sampling.
- e) The Navy is collecting additional soil gas samples to confirm the Phase I sampling results.

Actions that You Can Take to Reduce Exposure to Chemicals

- a) In accordance with the Bottled Water Advisory, use only bottled water for drinking, cooking, and brushing your teeth, and making ice.

Navy leadership is committed to your health and well-being. The U.S. and Italian governments have both made this study a top priority and we will keep you informed every step of the way. We appreciate your patience with this deliberate and complex process.

We encourage you to ask questions, attend Town Hall Meetings, check the website (<https://www.cnmc.navy.mil/Naples/Programs/HealthAwareness>), and use your chain of command for assistance in getting the answers you deserve. We have established an Environmental Health Information Office as a resource to help with your health related questions or concerns, which is located on the ground floor of Naval Hospital Naples, Room 1096, DSN 629-6071. CDR Tim Halenkamp, who runs this office, is also the Director of Occupational and Environmental Medicine and can be reached at DSN 314-626-6807 or Commercial 39-081-568-6807.

Attachment A

Overview of the Phase I Screening Risk Evaluation Approach

Comparison of Environmental Sampling Results to Risk-Based Screening Concentrations

To determine whether or not the sampling results for soil, soil gas, and tap water are potentially of concern to human health, the sampling results were compared to United States Environmental Protection Agency (USEPA) risk-based regional screening levels (RSLs). The RSLs incorporate many conservative assumptions about exposure to be protective of human health.

Concentrations for each chemical were compared to:

1. USEPA RSLs based on 30-year residential exposure
2. USEPA Maximum Contaminant Levels (MCLs) for Drinking Water

The USEPA RSLs are calculated based on carcinogenic (i.e., cancer) risks and noncarcinogenic (i.e., noncancer) health effects. Cancer risk is an estimate of how exposure to a chemical may increase the normal or expected rate of developing cancer in a population of people. The USEPA generally evaluates cancer risk¹ as follows:

- **Acceptable Risk** – A cancer risk of 1×10^{-6} (i.e., one person out of 1,000,000 will develop cancer) or less is considered safe (i.e., acceptable). Note: The USEPA generally also considers the range between one in 10,000 (1×10^{-4}) and one in 1,000,000 (1×10^{-6}) people as a safe (i.e., acceptable) range, and actions to reduce the risk may or may not be required based on various site-specific factors. The USEPA typically considers additional actions to reduce cancer risks that are close to or greater than one in 10,000 (1×10^{-4}) people.
- **Unacceptable Risk** – USEPA considers an increase of “more than” one additional case of cancer (or greater) in 10,000 (1×10^{-4}) people to be of concern (i.e., unacceptable).

Noncancer health effects are expressed by a number known as the “hazard quotient” or “HQ.” The HQ compares the amount of a chemical that people may have been exposed to over a specified time period with the amount that is considered to have no effect (i.e., safe). If people are exposed to an amount greater than that considered safe for a particular chemical, then the ratio will be greater than one. Because people can be

¹ For the purposes of the Phase I SRE, the Navy has decided to use only two categories to categorize risks (i.e., “Acceptable” or “Unacceptable”). See Appendix B for the definition of *Acceptable* and *Unacceptable* risks).

exposed to more than one chemical at a time, the HQs for different chemicals are added together to give an overall “Hazard Index” or “HI,” unless data is available to indicate that they should not be added together. USEPA policy considers chemical concentrations resulting in an HI above one to be of concern for developing potential noncancer health effects. Professional judgment must be used to evaluate the potential noncancer health effects related to the concentration of these chemicals to determine if actions to reduce the risk are needed.

Comparison of Environmental Sampling Results to Maximum Contaminant Levels (MCLs)

MCLs are maximum permissible levels of a contaminant in public water supplies. For private water supplies, MCLs are useful for determining potability. MCLs are protective of public health during a lifetime (70 years) for an individual who drinks two liters of water per day.

Attachment B

Risk Management Criteria

This Screening Risk Evaluation (SRE) characterizes the potential health risks associated with living at your residence for 30 years. This is generally a conservative assumption because typical tour lengths range from three to six years. The risk evaluation results were placed into one of two categories: 1) Acceptable Risks or 2) Unacceptable Risks. Based on the results of the SRE, the appropriate course of action will be taken to ensure the safety of U.S. Navy military and civilian personnel and their families. The criteria for each of the risk-management categories are defined below.

**United States Navy
Naples, Italy Phase I Screening Risk Evaluation
Risk Management Categories**

Criteria/ Actions	Acceptable Risks	Unacceptable Risks
Risk Criteria – for Residences Using Tap Water for Drinking, Cooking, Brushing Teeth, and Making Ice⁶	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). Applies to all chemicals. 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). Applies to all chemicals.
Risk Criteria – for Residences <u>NOT</u> Using Tap Water for Drinking, Cooking, Brushing Teeth, and Making Ice⁷	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). Applies only to Fecal Coliform and Total Coliforms (including Fecal Coliform and E. Coli). 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). Applies only to Fecal Coliform and Total Coliforms (including Fecal Coliform and E. Coli).

**United States Navy
Naples, Italy Phase I Screening Risk Evaluation
Risk Management Categories**

Criteria/ Actions	Acceptable Risks	Unacceptable Risks
	<p>Notes:</p> <ol style="list-style-type: none"> 1. Noncancer exceedance factors (NCEFs) were calculated by dividing the maximum detected concentrations by noncancer-based U.S. Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs). 2. Cancer exceedance factors (CEFs) were calculated by dividing the maximum detected concentrations by cancer-based USEPA RSLs. 3. The individual NCEFs and CEFs were summed to provide the total NCEF and total CEF. 4. An NCEF of 1 corresponds to a Hazard Index of 1. 5. A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million). A CEF of 10 corresponds to a cancer risk of 1×10^{-5} (one in a one hundred thousand). 6. The tap water RSLs used to evaluate residences that <u>USE</u> tap water for drinking, cooking, brushing teeth, and making ice were based on ingestion and inhalation of household uses (e.g., showering) of tap water. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate. 7. The tap water RSLs used to evaluate residences that <u>DO NOT</u> use tap water for drinking, cooking, brushing teeth, and making ice were based on inhalation of household uses (e.g., showering) of tap water only. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate.

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E.Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Data Qualifiers:

Blank (i.e., no qualifier) = The chemical was detected.

> = The chemical was detected.

J = The chemical was detected but the concentration reported is an estimated value.

U = The chemical was not detected.

< = The chemical was not detected.

-- = The chemical was not analyzed or no value was available.

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E.Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Data Qualifiers:

Blank (i.e., no qualifier) = The chemical was detected.

> = The chemical was detected.

J = The chemical was detected but the concentration reported is an estimated value.

U = The chemical was not detected.

< = The chemical was not detected.

-- = The chemical was not analyzed or no value was available.

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E.Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Data Qualifiers:

Blank (i.e., no qualifier) = The chemical was detected.

> = The chemical was detected.

J = The chemical was detected but the concentration reported is an estimated value.

U = The chemical was not detected.

< = The chemical was not detected.

INCREMENTAL RISK					0.03	0.05

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

BACKGROUND RISK					2.2	33.1
INCREMENTAL RISK					0.04	0.09

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

INCREMENTAL RISK					0.03	0.04

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

BACKGROUND RISK					1.8	30.0
INCREMENTAL RISK					0.03	0.1

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

INCREMENTAL RISK					0.04	0.1

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

INCREMENTAL RISK					0.04	0.02

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

TOTAL RISK				0	0
BACKGROUND RISK				0	0
INCREMENTAL RISK				0	0

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer- based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

INCREMENTAL RISK							0	0	0.2	4.5		

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

INCREMENTAL RISK					0.04	0.06

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

TOTAL RISK				0	0
BACKGROUND RISK				0	0
INCREMENTAL RISK				0	0

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

INCREMENTAL RISK					0.03	0.01

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

TOTAL RISK				0	0
BACKGROUND RISK				0	0
INCREMENTAL RISK				0	0

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

BACKGROUND RISK							0	0	0.4	93.6	
INCREMENTAL RISK							0	0	0.3	3.6	

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

Attachment E
Chemical Fact Sheets

**This page has been left blank intentionally
to allow for double-sided printing.**

This fact sheet answers the most frequently asked health questions (FAQs) about arsenic. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to higher than average levels of arsenic occur mostly in the workplace, near hazardous waste sites, or in areas with high natural levels. At high levels, inorganic arsenic can cause death. Exposure to lower levels for a long time can cause a discoloration of the skin and the appearance of small corns or warts. Arsenic has been found in at least 1,149 of the 1,684 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is arsenic?

Arsenic is a naturally occurring element widely distributed in the earth's crust. In the environment, arsenic is combined with oxygen, chlorine, and sulfur to form inorganic arsenic compounds. Arsenic in animals and plants combines with carbon and hydrogen to form organic arsenic compounds.

Inorganic arsenic compounds are mainly used to preserve wood. Copper chromated arsenate (CCA) is used to make "pressure-treated" lumber. CCA is no longer used in the U.S. for residential uses; it is still used in industrial applications. Organic arsenic compounds are used as pesticides, primarily on cotton fields and orchards.

What happens to arsenic when it enters the environment?

- Arsenic occurs naturally in soil and minerals and may enter the air, water, and land from wind-blown dust and may get into water from runoff and leaching.
- Arsenic cannot be destroyed in the environment. It can only change its form.
- Rain and snow remove arsenic dust particles from the air.
- Many common arsenic compounds can dissolve in water. Most of the arsenic in water will ultimately end up in soil or sediment.
- Fish and shellfish can accumulate arsenic; most of this arsenic is in an organic form called arsenobetaine that is much less harmful.

How might I be exposed to arsenic?

- Ingesting small amounts present in your food and water or breathing air containing arsenic.
- Breathing sawdust or burning smoke from wood treated with arsenic.
- Living in areas with unusually high natural levels of arsenic in rock.
- Working in a job that involves arsenic production or use, such as copper or lead smelting, wood treating, or pesticide application.

How can arsenic affect my health?

Breathing high levels of inorganic arsenic can give you a sore throat or irritated lungs.

Ingesting very high levels of arsenic can result in death. Exposure to lower levels can cause nausea and vomiting, decreased production of red and white blood cells, abnormal heart rhythm, damage to blood vessels, and a sensation of "pins and needles" in hands and feet.

Ingesting or breathing low levels of inorganic arsenic for a long time can cause a darkening of the skin and the appearance of small "corns" or "warts" on the palms, soles, and torso.

Skin contact with inorganic arsenic may cause redness and swelling.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Almost nothing is known regarding health effects of organic arsenic compounds in humans. Studies in animals show that some simple organic arsenic compounds are less toxic than inorganic forms. Ingestion of methyl and dimethyl compounds can cause diarrhea and damage to the kidneys

How likely is arsenic to cause cancer?

Several studies have shown that ingestion of inorganic arsenic can increase the risk of skin cancer and cancer in the liver, bladder, and lungs. Inhalation of inorganic arsenic can cause increased risk of lung cancer. The Department of Health and Human Services (DHHS) and the EPA have determined that inorganic arsenic is a known human carcinogen. The International Agency for Research on Cancer (IARC) has determined that inorganic arsenic is carcinogenic to humans.

How can arsenic affect children?

There is some evidence that long-term exposure to arsenic in children may result in lower IQ scores. There is also some evidence that exposure to arsenic in the womb and early childhood may increase mortality in young adults.

There is some evidence that inhaled or ingested arsenic can injure pregnant women or their unborn babies, although the studies are not definitive. Studies in animals show that large doses of arsenic that cause illness in pregnant females, can also cause low birth weight, fetal malformations, and even fetal death. Arsenic can cross the placenta and has been found in fetal tissues. Arsenic is found at low levels in breast milk.

How can families reduce the risks of exposure to arsenic?

If you use arsenic-treated wood in home projects, you should wear dust masks, gloves, and protective clothing to decrease exposure to sawdust.

- If you live in an area with high levels of arsenic in water or soil, you should use cleaner sources of water and limit contact with soil.
- If you work in a job that may expose you to arsenic, be aware that you may carry arsenic home on your clothing, skin, hair, or tools. Be sure to shower and change clothes before going home.

Is there a medical test to determine whether I've been exposed to arsenic?

There are tests available to measure arsenic in your blood, urine, hair, and fingernails. The urine test is the most reliable test for arsenic exposure within the last few days. Tests on hair and fingernails can measure exposure to high levels of arsenic over the past 6-12 months. These tests can determine if you have been exposed to above-average levels of arsenic. They cannot predict whether the arsenic levels in your body will affect your health.

Has the federal government made recommendations to protect human health?

The EPA has set limits on the amount of arsenic that industrial sources can release to the environment and has restricted or cancelled many of the uses of arsenic in pesticides. EPA has set a limit of 0.01 parts per million (ppm) for arsenic in drinking water.

The Occupational Safety and Health Administration (OSHA) has set a permissible exposure limit (PEL) of 10 micrograms of arsenic per cubic meter of workplace air (10 µg/m³) for 8 hour shifts and 40 hour work weeks.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about nickel. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Nickel is a naturally occurring element. Pure nickel is a hard, silvery-white metal used to make stainless steel and other metal alloys. Skin effects are the most common effects in people who are sensitive to nickel. Workers who breathed very large amounts of nickel compounds developed chronic bronchitis and lung and nasal sinus cancers. Nickel has been found in at least 882 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is nickel?

Nickel is a very abundant natural element. Pure nickel is a hard, silvery-white metal. Nickel can be combined with other metals, such as iron, copper, chromium, and zinc, to form alloys. These alloys are used to make coins, jewelry, and items such as valves and heat exchangers. Most nickel is used to make stainless steel.

Nickel can combine with other elements such as chlorine, sulfur, and oxygen to form nickel compounds. Many nickel compounds dissolve fairly easy in water and have a green color. Nickel compounds are used for nickel plating, to color ceramics, to make some batteries, and as substances known as catalysts that increase the rate of chemical reactions. Nickel is found in all soil and is emitted from volcanoes. Nickel is also found in meteorites and on the ocean floor. Nickel and its compounds have no characteristic odor or taste.

What happens to nickel when it enters the environment?

- Nickel is released into the atmosphere by industries that make or use nickel, nickel alloys, or nickel compounds. It is also released into the atmosphere by oil-burning power plants, coal-burning power plants, and trash incinerators.
- In the air, it attaches to small particles of dust that settle to the ground or are taken out of the air in rain or snow; this usually takes many days.

- Nickel released in industrial waste water ends up in soil or sediment where it strongly attaches to particles containing iron or manganese.
- Nickel does not appear to accumulate in fish or in other animals used as food.

How might I be exposed to nickel?

- By eating food containing nickel, which is the major source of exposure for most people.
- By skin contact with soil, bath or shower water, or metals containing nickel, as well as by handling coins or touching jewelry containing nickel.
- By drinking water that contains small amounts of nickel.
- By breathing air or smoking tobacco containing nickel.
- Higher exposure may occur if you work in industries that process or use nickel.

How can nickel affect my health?

The most common harmful health effect of nickel in humans is an allergic reaction. Approximately 10-20% of the population is sensitive to nickel. People can become sensitive to nickel when jewelry or other things containing it are in direct contact with the skin for a long time. Once a person is sensitized to nickel, further contact with the metal may produce a reaction. The most common reaction is a skin rash at the site of contact. The skin rash may also

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

occur at a site away from the site of contact. Less frequently, some people who are sensitive to nickel have asthma attacks following exposure to nickel. Some sensitized people react when they consume food or water containing nickel or breathe dust containing it.

People working in nickel refineries or nickel-processing plants have experienced chronic bronchitis and reduced lung function. These persons breathed amounts of nickel much higher than levels found normally in the environment.

Workers who drank water containing high amounts of nickel had stomach ache and suffered adverse effects to their blood and kidneys.

Damage to the lung and nasal cavity has been observed in rats and mice breathing nickel compounds. Eating or drinking large amounts of nickel has caused lung disease in dogs and rats and has affected the stomach, blood, liver, kidneys, and immune system in rats and mice, as well as their reproduction and development.

How likely is nickel to cause cancer?

Cancers of the lung and nasal sinus have resulted when workers breathed dust containing high levels of nickel compounds while working in nickel refineries or nickel processing plants. The Department of Health and Human Services (DHHS) has determined that nickel metal may reasonably be anticipated to be a carcinogen and that nickel compounds are known human carcinogens. The International Agency for Research on Cancer (IARC) has determined that some nickel compounds are carcinogenic to humans and that metallic nickel may possibly be carcinogenic to humans. The EPA has determined that nickel refinery dust and nickel subsulfide are human carcinogens.

How can nickel affect children?

It is likely that the health effects seen in children exposed to nickel will be similar to those seen in adults. We do not know whether children differ from adults in their susceptibility to nickel. Human studies that examined whether nickel can harm the fetus are inconclusive. Animal studies have found increases in newborn deaths and

decreased newborn weight after ingesting very high amounts of nickel. Nickel can be transferred from the mother to an infant in breast milk and can cross the placenta.

How can families reduce the risks of exposure to nickel?

- Avoiding jewelry containing nickel will eliminate risks of exposure to this source of the metal.
- Exposures of the general population from other sources, such as foods and drinking water, are almost always too low to be of concern.

Is there a medical test to determine whether I've been exposed to nickel?

There are tests available to measure nickel in your blood, feces, and urine. More nickel was measured in the urine of workers who were exposed to nickel compounds that dissolve easily in water than in the urine of workers exposed to nickel compounds that are hard to dissolve. This means that it is easier to tell if you have been exposed to soluble nickel compounds than less-soluble compounds. The nickel measurements do not accurately predict potential health effects from exposure to nickel.

Has the federal government made recommendations to protect human health?

The EPA recommends that drinking water should contain no more than 0.1 milligrams of nickel per liter of water (0.1 mg/L). To protect workers, the Occupational Safety and Health Administration (OSHA) has set a limit of 1 mg of nickel per cubic meter of air (1 mg/m³) for metallic nickel and nickel compounds in workplace air during an 8-hour workday, 40-hour workweek.

You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about tetrachloroethylene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Tetrachloroethylene is a manufactured chemical used for dry cleaning and metal degreasing. Exposure to very high concentrations of tetrachloroethylene can cause dizziness, headaches, sleepiness, confusion, nausea, difficulty in speaking and walking, unconsciousness, and death. Tetrachloroethylene has been found in at least 771 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is tetrachloroethylene?

(Pronounced tět'rə-klôr' 0-ěth'ə-lēn')

Tetrachloroethylene is a manufactured chemical that is widely used for dry cleaning of fabrics and for metal-degreasing. It is also used to make other chemicals and is used in some consumer products.

Other names for tetrachloroethylene include perchloroethylene, PCE, and tetrachloroethene. It is a nonflammable liquid at room temperature. It evaporates easily into the air and has a sharp, sweet odor. Most people can smell tetrachloroethylene when it is present in the air at a level of 1 part tetrachloroethylene per million parts of air (1 ppm) or more, although some can smell it at even lower levels.

What happens to tetrachloroethylene when it enters the environment?

- Much of the tetrachloroethylene that gets into water or soil evaporates into the air.
- Microorganisms can break down some of the tetrachloroethylene in soil or underground water.
- In the air, it is broken down by sunlight into other chemicals or brought back to the soil and water by rain.
- It does not appear to collect in fish or other animals that live in water.

How might I be exposed to tetrachloroethylene?

- When you bring clothes from the dry cleaners, they will release small amounts of tetrachloroethylene into the air.
- When you drink water containing tetrachloroethylene, you are exposed to it.

How can tetrachloroethylene affect my health?

High concentrations of tetrachloroethylene (particularly in closed, poorly ventilated areas) can cause dizziness, headache, sleepiness, confusion, nausea, difficulty in speaking and walking, unconsciousness, and death.

Irritation may result from repeated or extended skin contact with it. These symptoms occur almost entirely in work (or hobby) environments when people have been accidentally exposed to high concentrations or have intentionally used tetrachloroethylene to get a "high."

In industry, most workers are exposed to levels lower than those causing obvious nervous system effects. The health effects of breathing in air or drinking water with low levels of tetrachloroethylene are not known.

Results from some studies suggest that women who work in dry cleaning industries where exposures to tetrachloroethyl-

ToxFAQs Internet home page via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

ene can be quite high may have more menstrual problems and spontaneous abortions than women who are not exposed. However, it is not known if tetrachloroethylene was responsible for these problems because other possible causes were not considered.

Results of animal studies, conducted with amounts much higher than those that most people are exposed to, show that tetrachloroethylene can cause liver and kidney damage. Exposure to very high levels of tetrachloroethylene can be toxic to the unborn pups of pregnant rats and mice. Changes in behavior were observed in the offspring of rats that breathed high levels of the chemical while they were pregnant.

How likely is tetrachloroethylene to cause cancer?

The Department of Health and Human Services (DHHS) has determined that tetrachloroethylene may reasonably be anticipated to be a carcinogen. Tetrachloroethylene has been shown to cause liver tumors in mice and kidney tumors in male rats.

Is there a medical test to show whether I've been exposed to tetrachloroethylene?

One way of testing for tetrachloroethylene exposure is to measure the amount of the chemical in the breath, much the same way breath-alcohol measurements are used to determine the amount of alcohol in the blood.

Because it is stored in the body's fat and slowly released into the bloodstream, tetrachloroethylene can be detected in the breath for weeks following a heavy exposure.

Tetrachloroethylene and trichloroacetic acid (TCA), a breakdown product of tetrachloroethylene, can be detected in the blood. These tests are relatively simple to perform. These tests aren't available at most doctors' offices, but can be per-

formed at special laboratories that have the right equipment.

Because exposure to other chemicals can produce the same breakdown products in the urine and blood, the tests for breakdown products cannot determine if you have been exposed to tetrachloroethylene or the other chemicals.

Has the federal government made recommendations to protect human health?

The EPA maximum contaminant level for the amount of tetrachloroethylene that can be in drinking water is 0.005 milligrams tetrachloroethylene per liter of water (0.005 mg/L).

The Occupational Safety and Health Administration (OSHA) has set a limit of 100 ppm for an 8-hour workday over a 40-hour workweek.

The National Institute for Occupational Safety and Health (NIOSH) recommends that tetrachloroethylene be handled as a potential carcinogen and recommends that levels in workplace air should be as low as possible.

Glossary

Carcinogen: A substance with the ability to cause cancer.

CAS: Chemical Abstracts Service.

Milligram (mg): One thousandth of a gram.

Nonflammable: Will not burn.

This ToxFAQs information is taken from the 1997 Toxicological Profile for Tetrachloroethylene (update) produced by the Agency for Toxic Substances and Disease Registry, Public Health Service, U.S. Department of Health and Human Services, Public Health Service in Atlanta, GA.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html> ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about chlorinated dibenzo-p-dioxins (CDDs). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to chlorinated dibenzo-p-dioxins (CDDs) (75 chemicals) occurs mainly from eating food that contains the chemicals. One chemical in this group, 2,3,7,8-tetrachlorodibenzo-p-dioxin or 2,3,7,8-TCDD, has been shown to be very toxic in animal studies. It causes effects on the skin and may cause cancer in people. This chemical has been found in at least 91 of 1,467 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What are CDDs?

CDDs are a family of 75 chemically related compounds commonly known as chlorinated dioxins. One of these compounds is called 2,3,7,8-TCDD. It is one of the most toxic of the CDDs and is the one most studied.

In the pure form, CDDs are crystals or colorless solids. CDDs enter the environment as mixtures containing a number of individual components. 2,3,7,8-TCDD is odorless and the odors of the other CDDs are not known.

CDDs are not intentionally manufactured by industry except for research purposes. They (mainly 2,3,7,8-TCDD) may be formed during the chlorine bleaching process at pulp and paper mills. CDDs are also formed during chlorination by waste and drinking water treatment plants. They can occur as contaminants in the manufacture of certain organic chemicals. CDDs are released into the air in emissions from municipal solid waste and industrial incinerators.

What happens to CDDs when they enter the environment?

- When released into the air, some CDDs may be transported long distances, even around the globe.

- When released in waste waters, some CDDs are broken down by sunlight, some evaporate to air, but most attach to soil and settle to the bottom sediment in water.
- CDD concentrations may build up in the food chain, resulting in measurable levels in animals.

How might I be exposed to CDDs?

- Eating food, primarily meat, dairy products, and fish, makes up more than 90% of the intake of CDDs for the general population.
- Breathing low levels in air and drinking low levels in water.
- Skin contact with certain pesticides and herbicides.
- Living near an uncontrolled hazardous waste site containing CDDs or incinerators releasing CDDs.
- Working in industries involved in producing certain pesticides containing CDDs as impurities, working at paper and pulp mills, or operating incinerators.

How can CDDs affect my health?

The most noted health effect in people exposed to large amounts of 2,3,7,8-TCDD is chloracne. Chloracne is a severe skin disease with acne-like lesions that occur mainly on the face and upper body. Other skin effects noted in people exposed to high doses of 2,3,7,8-TCDD include skin rashes, dis-

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

coloration, and excessive body hair. Changes in blood and urine that may indicate liver damage also are seen in people. Exposure to high concentrations of CDDs may induce long-term alterations in glucose metabolism and subtle changes in hormonal levels.

In certain animal species, 2,3,7,8-TCDD is especially harmful and can cause death after a single exposure. Exposure to lower levels can cause a variety of effects in animals, such as weight loss, liver damage, and disruption of the endocrine system. In many species of animals, 2,3,7,8-TCDD weakens the immune system and causes a decrease in the system's ability to fight bacteria and viruses. In other animal studies, exposure to 2,3,7,8-TCDD has caused reproductive damage and birth defects. Some animal species exposed to CDDs during pregnancy had miscarriages and the offspring of animals exposed to 2,3,7,8-TCDD during pregnancy often had severe birth defects including skeletal deformities, kidney defects, and weakened immune responses.

How likely are CDDs to cause cancer?

Several studies suggest that exposure to 2,3,7,8-TCDD increases the risk of several types of cancer in people. Animal studies have also shown an increased risk of cancer from exposure to 2,3,7,8-TCDD.

The World Health Organization (WHO) has determined that 2,3,7,8-TCDD is a human carcinogen.

The Department of Health and Human Services (DHHS) has determined that 2,3,7,8-TCDD may reasonably be anticipated to cause cancer.

How can CDDs affect children?

Very few studies have looked at the effects of CDDs on children. Chloracne has been seen in children exposed to high levels of CDDs. We don't know if CDDs affect the ability of people to have children or if it causes birth defects, but given the effects observed in animal studies, this cannot be ruled out.

How can families reduce the risk of exposure to CDDs?

- Children should avoid playing in soils near uncontrolled hazardous waste sites.
- Discourage children from eating dirt or putting toys or other objects in their mouths.
- Everyone should wash hands frequently if playing or working near uncontrolled hazardous waste sites.
- For new mothers and young children, restrict eating foods from the proximity of uncontrolled sites with known CDDs.

Is there a medical test to show whether I've been exposed to CDDs?

Tests are available to measure CDD levels in body fat, blood, and breast milk, but these tests are not routinely available. Most people have low levels of CDDs in their body fat and blood, and levels considerably above these levels indicate past exposure to above-normal levels of 2,3,7,8-TCDD. Although CDDs stay in body fat for a long time, tests cannot be used to determine when exposure occurred.

Has the federal government made recommendations to protect human health?

The EPA has set a limit of 0.00003 micrograms of 2,3,7,8-TCDD per liter of drinking water (0.00003 µg/L). Discharges, spills, or accidental releases of 1 pound or more of 2,3,7,8-TCDD must be reported to EPA. The Food and Drug Administration (FDA) recommends against eating fish and shellfish with levels of 2,3,7,8-TCDD greater than 50 parts per trillion (50 ppt).

PHASE I SCREENING RISK EVALUATION FOR PARCO LE GINESTRE RESIDENCES

**This page has been left blank intentionally
to allow for double-sided printing.**

NAPLES Public Health Evaluation

U.S. Navy, Naples Housing Office Premise ID: Le Ginestre

Dear Le Ginestre Resident:

SUBJECT: Phase I Screening Risk Evaluation for Le Ginestre Residences

The Navy Public Health Evaluation Team has completed a Screening Risk Evaluation (SRE) of soil, soil gas, tap water, and irrigation well water samples that were collected at Parco Le Ginestre residences and common areas from 07/03/2008 to 09/18/2008 (See Figure 1). The purpose of the SRE is to evaluate the potential human health risks to Navy personnel and their families residing in the Naples area as a result of public health concerns that could be related to improper refuse disposal (including open burning) and hazardous waste disposal practices. This memo summarizes the results of the investigation that was performed at Parco Le Ginestre residences and common areas. These sampling results were compared to U.S. Environmental Protection Agency (USEPA) health standards and of the fourteen locations sampled in the Parco, seven have been assessed to be Acceptable and seven have been assessed to be Unacceptable.

SCREENING RISK EVALUATION RESULTS

The environmental sampling results for soil, soil gas, tap water, and irrigation well water were compared to risk-based regional screening levels (RSLs) and drinking water standards (maximum contaminant levels [MCLs]) to evaluate potential risks to human health. These levels are considered by the USEPA to be protective of human health. Concentrations of chemicals in soil, soil gas, and tap water that exceed these levels may be of concern. Please see Attachment A for further discussion of the SRE approach.

These sampling results are being used as the basis for making recommendations for your residence. They will also be used as part of the overall effort in evaluating potential risks in the Naples area. The two potential outcomes of the SRE are that risks at your residence were: 1) Acceptable or 2) Unacceptable. Please see Attachment B for further discussion of these risk categories. This determination is based on a number of factors and assumes that an individual lives at the residence for 30-years, which is typically used by the USEPA to evaluate residential locations. Your actual risk may be significantly less than the risks presented in this memo. For example, if you live at this location for only three years and do not drink the tap water, then your risks will be significantly less than those presented in this memo.

Finally, risks presented in this SRE are based on a single sampling event. A single sample only provides a "snapshot" of concentrations that are present in soil, soil gas, and tap water. One sample may or may not be representative of the soil, soil gas, and tap water concentrations present each location. Please see Attachment C for the sampling results for all Parco Le Ginestre locations.

SUBJECT: Phase I Screening Risk Evaluation for Le Ginestre Residences

Typically, in SRE reports, total risks are determined by calculating the potential risk for all of the various ways one might be exposed to contaminants, which are referred to as exposure pathways such as ingestion, inhalation, dermal contact, et cetera. For Naples, Navy leadership has implemented a Bottled Water Advisory and is requiring landlords to provide a water service from Navy-approved sources to eliminate the tap water ingestion exposure pathway. Therefore, we are calculating the risk two ways, assuming exposure via the ingestion pathway, and assuming no exposure via the ingestion pathway. Both of these risk determinations are described below and a table presenting the comparison of the environmental sampling results collected at Parco Le Ginestre and applicable screening concentrations is presented in Attachment D.

Risks Calculated Assuming that Tap Water IS Used for Drinking, Cooking, Brushing Teeth and Making Ice

If the tap water at Parco Le Ginestre is used for drinking, cooking, brushing teeth, and making ice (in addition to other household uses), then based on USEPA RSLs and MCLs, the risks at three out of ten residences are Acceptable and seven are Unacceptable because the total cancer risk exceedance factor (summed based on exposure to soil, soil gas, and tap water) was greater than 10 and due to concentrations of chemicals detected in soil gas and tap water. Of the nearly 220 chemicals that were tested in soil and tap water and the approximately 40 that were tested for in soil gas, five were detected at levels of potential concern¹.

Risks Calculated Assuming that Tap Water IS NOT Used for Drinking, Cooking, Brushing Teeth and Making Ice

The Navy has determined that the tap water in Naples should not be used for drinking, cooking, brushing teeth, or making ice. Therefore, if the tap water at Parco Le Ginestre is not used for drinking, cooking, brushing teeth, and making ice (i.e., tap water is only used for other household uses such as showering or washing clothes), then based on USEPA RSLs and MCLs, the risks at four out of ten residences are Acceptable and six are Unacceptable because the total cancer risk exceedance factor (summed based on exposure to soil, soil gas, and tap water) was greater than 10 and due to concentrations of chemicals detected in soil gas and tap water. Of the nearly 220 chemicals that were tested in soil and tap water and approximately 40 that were tested for in soil gas, three were detected at a level of potential concern¹.

Summary of Chemical-Specific Results

In soil gas, tetrachloroethene exceeded its RSL at locations LE01, LE03, LE07, LE11, LE19, and LE20 and chloroform exceeded its RSL at location LE08. In tap water, total dioxin/furans exceeded its RSL at locations LE19 and LE20, chloroform exceeded its RSL at locations LE01, LE03, LE07, LE10, LE11, LE15, LE19 and LE20, dibromochloromethane exceeded its RSL at locations LE01, LE10 and LE20, tetrachloroethene exceeded its RSL at location LE01, and total coliform bacteria exceeded the MCL at location LE19. Please see Table 1 for a summary of Parco Le Ginestre residence risks by location.

¹ This excludes naturally-occurring chemicals, such as arsenic.

SUBJECT: Phase I Screening Risk Evaluation for Le Ginestre Residences

- 1) The tetrachloroethene ingestion RSL exceedance is mitigated by the use of bottled water. The tetrachloroethene inhalation RSL exceedance in tap water cannot be totally mitigated by bottled water; there will be some exposure via inhalation due to household uses of tap water (e.g., washing clothes and showering). Tetrachloroethene is a solvent commonly used to dry clean clothes.
- 2) The chloroform inhalation RSL exceedance in tap water cannot be totally mitigated by bottled water; there will be some exposure via inhalation due to household uses of tap water (e.g., washing clothes and showering). In the past, chloroform was used as an inhaled anesthetic during surgery, but it isn't used that way today. Today, chloroform is used to make other chemicals and can also be formed as a byproduct when chlorine is added to water to kill bacteria.
- 3) The total dioxin/furans ingestion RSL exceedances are mitigated by the use of bottled water. Dioxins/Furans are a group of chemicals that are called chlorinated dibenzo-p-dioxins and dibenzo-p-furans. These chemicals can be produced during incomplete burning of wood or materials such as garbage.
- 4) The dibromochloromethane ingestion RSL exceedances are mitigated by the use of bottled water. Dibromochloromethane is typically formed as a byproduct when chlorine is added to water to kill bacteria.
- 5) The total coliform MCL exceedance cannot be totally mitigated by bottled water, there will be some exposure via household uses of tap water (e.g., showering). Total coliforms are a group of bacteria that are used as indicators of possible sewage contamination because they are commonly found in human and animal feces. Although they are generally not harmful themselves, they indicate the possible presence of pathogenic (disease-causing) bacteria, viruses, and protozoans that also live in human and animal digestive systems.

For more information on these chemicals, please see Attachment E.

It should be noted that the concentrations of naturally-occurring arsenic in soil and tap water were above RSLs at all Parco Le Ginestre residences.

- 1) Arsenic in soil and tap water is often associated with volcanic activity. This is similar to areas in the United States (e.g., Puget Sound, Washington).

USEPA risk assessors also consider background concentrations of naturally-occurring metals (identified as Inorganics in Attachment D), such as arsenic, when evaluating risks. The concentrations of these naturally-occurring substances found at your residence were not included in risk-management decisions. The concentrations of metals in soil at your residence were similar to background concentrations found in the Naples area. The concentrations of arsenic in tap water were below the MCL for all Parco Le Ginestre residences. For more information on arsenic, please see Attachment E.

SUBJECT: Phase I Screening Risk Evaluation for Le Ginestre Residences

The risk-management decision (i.e., Acceptable or Unacceptable) presented in this memo is based on the Incremental Risk (i.e., the risks not including natural background). See the footnotes in Attachment D for more information.

Risks Calculated for Parco Le Ginestre Common Areas

Three soil samples (locations LE21, LE22 and LE23) and one water sample from an irrigation well (location LEIW01) were collected from a common area. These samples were also compared to USEPA RSLs and MCLs to evaluate potential risks to human health. The risks at all three soil sample locations have been assessed to be Acceptable. Irrigation well water is not being used for human consumption, however, if it were used for human consumption the risk would be Unacceptable. Please see Table 1 for a summary of Parco Le Ginestre residence risk by location.

None of the nearly 220 chemicals that were tested in soil were detected at levels of potential concern in the common areas (locations LE21, LE22 and LE23). However, the concentrations of naturally-occurring arsenic in soil were above its RSL. For details on naturally-occurring arsenic, please see the Summary of Chemical-Specific Results section. The concentrations of metals at these locations were similar to background concentrations found in the Naples area. For more information on arsenic, please see Attachment E.

Of the nearly 220 chemicals that were tested for in the irrigation well water, eight were detected at levels of potential concern¹. Nitrate, total dioxin/furans, zinc, bis(2-ethylhexyl)phthalate and tetrachloroethene exceeded RSLs. Nitrate, fecal coliform, total coliforms, uranium and bis(2-ethylhexyl)phthalate exceeded MCLs. Naturally-occurring arsenic was also present in the well water but at a concentration below the MCL. For more information on these chemicals, please see Attachment E.

Actions that the Navy is Taking Based on the Sampling Results

Based on the results of the environmental sampling performed at Parco Le Ginestre, the following actions have been or will be implemented:

- a) Bottled water will continue to be provided by the Navy until such time as the Navy's lease for this property is modified to require the landlord to provide containerized water.
- b) The bottled water advisory issued in 2008 is still in place.
- c) The Navy will ensure any water holding tanks and associated plumbing are regularly cleaned and disinfected.
- d) Italian authorities have been and will continue to be notified of the results of the environmental sampling.
- e) The Navy is collecting additional soil gas samples to confirm sampling results.
- f) Signs will be posted warning people that the irrigation well on-site is non-potable.

SUBJECT: Phase I Screening Risk Evaluation for Le Ginestre Residences

Actions that You Can Take to Reduce Exposure to Chemicals

- a) In accordance with the Bottled Water Advisory, use only bottled water for drinking, cooking, and brushing your teeth, and making ice.

Navy leadership is committed to your health and well-being. The U.S. and Italian governments have both made this study a top priority and we will keep you informed every step of the way. We appreciate your patience with this deliberate and complex process.

We encourage you to ask questions, attend Town Hall Meetings, check the website (<https://www.cnmc.navy.mil/Naples/Programs/HealthAwareness>), and use your chain of command for assistance in getting the answers you deserve. We have established an Environmental Health Information Office as a resource to help with your health related questions or concerns, which is located on the ground floor of Naval Hospital Naples, Room 1096, DSN 629-6071. CDR Tim Halenkamp, who runs this office, is also the Director of Occupational and Environmental Medicine and can be reached at DSN 314-626-6807 or Commercial 39-081-568-6807.

Attachment A

Overview of the Phase I Screening Risk Evaluation Approach

Comparison of Environmental Sampling Results to Risk-Based Screening Concentrations

To determine whether or not the sampling results for soil, soil gas, and tap water are potentially of concern to human health, the sampling results were compared to United States Environmental Protection Agency (USEPA) risk-based regional screening levels (RSLs). The RSLs incorporate many conservative assumptions about exposure to be protective of human health.

Concentrations for each chemical were compared to:

1. USEPA RSLs based on 30-year residential exposure
2. USEPA Maximum Contaminant Levels (MCLs) for Drinking Water

The USEPA RSLs are calculated based on carcinogenic (i.e., cancer) risks and noncarcinogenic (i.e., noncancer) health effects. Cancer risk is an estimate of how exposure to a chemical may increase the normal or expected rate of developing cancer in a population of people. The USEPA generally evaluates cancer risk¹ as follows:

- **Acceptable Risk** – A cancer risk of 1×10^{-6} (i.e., one person out of 1,000,000 will develop cancer) or less is considered safe (i.e., acceptable). Note: The USEPA generally also considers the range between one in 10,000 (1×10^{-4}) and one in 1,000,000 (1×10^{-6}) people as a safe (i.e., acceptable) range, and actions to reduce the risk may or may not be required based on various site-specific factors. The USEPA typically considers additional actions to reduce cancer risks that are close to or greater than one in 10,000 (1×10^{-4}) people.
- **Unacceptable Risk** – USEPA considers an increase of “more than” one additional case of cancer (or greater) in 10,000 (1×10^{-4}) people to be of concern (i.e., unacceptable).

Noncancer health effects are expressed by a number known as the “hazard quotient” or “HQ.” The HQ compares the amount of a chemical that people may have been exposed to over a specified time period with the amount that is considered to have no effect (i.e., safe). If people are exposed to an amount greater than that considered safe for a particular chemical, then the ratio will be greater than one. Because people can be

¹ For the purposes of the Phase I SRE, the Navy has decided to use only two categories to categorize risks (i.e., “Acceptable” or “Unacceptable”). See Appendix B for the definition of *Acceptable* and *Unacceptable* risks).

exposed to more than one chemical at a time, the HQs for different chemicals are added together to give an overall “Hazard Index” or “HI,” unless data is available to indicate that they should not be added together. USEPA policy considers chemical concentrations resulting in an HI above one to be of concern for developing potential noncancer health effects. Professional judgment must be used to evaluate the potential noncancer health effects related to the concentration of these chemicals to determine if actions to reduce the risk are needed.

Comparison of Environmental Sampling Results to Maximum Contaminant Levels (MCLs)

MCLs are maximum permissible levels of a contaminant in public water supplies. For private water supplies, MCLs are useful for determining potability. MCLs are protective of public health during a lifetime (70 years) for an individual who drinks two liters of water per day.

Attachment B

Risk Management Criteria

This Screening Risk Evaluation (SRE) characterizes the potential health risks associated with living at your residence for 30 years. This is generally a conservative assumption because typical tour lengths range from three to six years. The risk evaluation results were placed into one of two categories: 1) Acceptable Risks or 2) Unacceptable Risks. Based on the results of the SRE, the appropriate course of action will be taken to ensure the safety of U.S. Navy military and civilian personnel and their families. The criteria for each of the risk-management categories are defined below.

**United States Navy
Naples, Italy Phase I Screening Risk Evaluation
Risk Management Categories**

Criteria/ Actions	Acceptable Risks	Unacceptable Risks
Risk Criteria – for Residences Using Tap Water for Drinking, Cooking, Brushing Teeth, and Making Ice⁶	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). Applies to all chemicals. 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). Applies to all chemicals.
Risk Criteria – for Residences <u>NOT</u> Using Tap Water for Drinking, Cooking, Brushing Teeth, and Making Ice⁷	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). Applies only to Fecal Coliform and Total Coliforms (including Fecal Coliform and E. Coli). 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). Applies only to Fecal Coliform and Total Coliforms (including Fecal Coliform and E. Coli).

Risk Management Categories**

Criteria/ Actions	Acceptable Risks	Unacceptable Risks
	<p>Notes:</p> <ol style="list-style-type: none"> 1. Noncancer exceedance factors (NCEFs) were calculated by dividing the maximum detected concentrations by noncancer-based U.S. Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs). 2. Cancer exceedance factors (CEFs) were calculated by dividing the maximum detected concentrations by cancer-based USEPA RSLs. 3. The individual NCEFs and CEFs were summed to provide the total NCEF and total CEF. 4. An NCEF of 1 corresponds to a Hazard Index of 1. 5. A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million). A CEF of 10 corresponds to a cancer risk of 1×10^{-5} (one in a one hundred thousand). 6. The tap water RSLs used to evaluate residences that <u>USE</u> tap water for drinking, cooking, brushing teeth, and making ice were based on ingestion and inhalation of household uses (e.g., showering) of tap water. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate. 7. The tap water RSLs used to evaluate residences that <u>DO NOT</u> use tap water for drinking, cooking, brushing teeth, and making ice were based on inhalation of household uses (e.g., showering) of tap water only. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate.

-- = The chemical was not analyzed or no value was available.

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E.Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Data Qualifiers:

Blank (i.e., no qualifier) = The chemical was detected.

> = The chemical was detected.

J = The chemical was detected but the concentration reported is an estimated value.

U = The chemical was not detected.

< = The chemical was not detected.

INCREMENTAL RISK					0.03	0.04

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

				TOTAL RISK	0.9	14.5
				BACKGROUND RISK	0.9	14.5
				INCREMENTAL RISK	0.02	0.009

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

INCREMENTAL RISK				0.01	9.9

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

INCREMENTAL RISK							0.001	1.0	0.6	1.7		

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

INCREMENTAL RISK					0.04	0.02

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

BACKGROUND RISK					1.2	20.0
INCREMENTAL RISK					0.03	0.10

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

INCREMENTAL RISK							0.002	1.9	0.2	3.3		

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

TOTAL RISK					2.2	47.2
BACKGROUND RISK					2.2	47.2
INCREMENTAL RISK					0.04	0.05

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

Attachment E
Chemical Fact Sheets

**This page has been left blank intentionally
to allow for double-sided printing.**

This fact sheet answers the most frequently asked health questions (FAQs) about arsenic. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to higher than average levels of arsenic occur mostly in the workplace, near hazardous waste sites, or in areas with high natural levels. At high levels, inorganic arsenic can cause death. Exposure to lower levels for a long time can cause a discoloration of the skin and the appearance of small corns or warts. Arsenic has been found in at least 1,149 of the 1,684 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is arsenic?

Arsenic is a naturally occurring element widely distributed in the earth's crust. In the environment, arsenic is combined with oxygen, chlorine, and sulfur to form inorganic arsenic compounds. Arsenic in animals and plants combines with carbon and hydrogen to form organic arsenic compounds.

Inorganic arsenic compounds are mainly used to preserve wood. Copper chromated arsenate (CCA) is used to make "pressure-treated" lumber. CCA is no longer used in the U.S. for residential uses; it is still used in industrial applications. Organic arsenic compounds are used as pesticides, primarily on cotton fields and orchards.

What happens to arsenic when it enters the environment?

- Arsenic occurs naturally in soil and minerals and may enter the air, water, and land from wind-blown dust and may get into water from runoff and leaching.
- Arsenic cannot be destroyed in the environment. It can only change its form.
- Rain and snow remove arsenic dust particles from the air.
- Many common arsenic compounds can dissolve in water. Most of the arsenic in water will ultimately end up in soil or sediment.
- Fish and shellfish can accumulate arsenic; most of this arsenic is in an organic form called arsenobetaine that is much less harmful.

How might I be exposed to arsenic?

- Ingesting small amounts present in your food and water or breathing air containing arsenic.
- Breathing sawdust or burning smoke from wood treated with arsenic.
- Living in areas with unusually high natural levels of arsenic in rock.
- Working in a job that involves arsenic production or use, such as copper or lead smelting, wood treating, or pesticide application.

How can arsenic affect my health?

Breathing high levels of inorganic arsenic can give you a sore throat or irritated lungs.

Ingesting very high levels of arsenic can result in death. Exposure to lower levels can cause nausea and vomiting, decreased production of red and white blood cells, abnormal heart rhythm, damage to blood vessels, and a sensation of "pins and needles" in hands and feet.

Ingesting or breathing low levels of inorganic arsenic for a long time can cause a darkening of the skin and the appearance of small "corns" or "warts" on the palms, soles, and torso.

Skin contact with inorganic arsenic may cause redness and swelling.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Almost nothing is known regarding health effects of organic arsenic compounds in humans. Studies in animals show that some simple organic arsenic compounds are less toxic than inorganic forms. Ingestion of methyl and dimethyl compounds can cause diarrhea and damage to the kidneys

How likely is arsenic to cause cancer?

Several studies have shown that ingestion of inorganic arsenic can increase the risk of skin cancer and cancer in the liver, bladder, and lungs. Inhalation of inorganic arsenic can cause increased risk of lung cancer. The Department of Health and Human Services (DHHS) and the EPA have determined that inorganic arsenic is a known human carcinogen. The International Agency for Research on Cancer (IARC) has determined that inorganic arsenic is carcinogenic to humans.

How can arsenic affect children?

There is some evidence that long-term exposure to arsenic in children may result in lower IQ scores. There is also some evidence that exposure to arsenic in the womb and early childhood may increase mortality in young adults.

There is some evidence that inhaled or ingested arsenic can injure pregnant women or their unborn babies, although the studies are not definitive. Studies in animals show that large doses of arsenic that cause illness in pregnant females, can also cause low birth weight, fetal malformations, and even fetal death. Arsenic can cross the placenta and has been found in fetal tissues. Arsenic is found at low levels in breast milk.

How can families reduce the risks of exposure to arsenic?

If you use arsenic-treated wood in home projects, you should wear dust masks, gloves, and protective clothing to decrease exposure to sawdust.

- If you live in an area with high levels of arsenic in water or soil, you should use cleaner sources of water and limit contact with soil.
- If you work in a job that may expose you to arsenic, be aware that you may carry arsenic home on your clothing, skin, hair, or tools. Be sure to shower and change clothes before going home.

Is there a medical test to determine whether I've been exposed to arsenic?

There are tests available to measure arsenic in your blood, urine, hair, and fingernails. The urine test is the most reliable test for arsenic exposure within the last few days. Tests on hair and fingernails can measure exposure to high levels of arsenic over the past 6-12 months. These tests can determine if you have been exposed to above-average levels of arsenic. They cannot predict whether the arsenic levels in your body will affect your health.

Has the federal government made recommendations to protect human health?

The EPA has set limits on the amount of arsenic that industrial sources can release to the environment and has restricted or cancelled many of the uses of arsenic in pesticides. EPA has set a limit of 0.01 parts per million (ppm) for arsenic in drinking water.

The Occupational Safety and Health Administration (OSHA) has set a permissible exposure limit (PEL) of 10 micrograms of arsenic per cubic meter of workplace air (10 µg/m³) for 8 hour shifts and 40 hour work weeks.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology and Environmental Medicine, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-800-232-4636, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about bromoform and dibromochloromethane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because these substances may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Bromoform and dibromochloromethane are formed as by-products when chlorine is added to water supply systems. High levels of bromoform or dibromochloromethane can damage the liver and kidneys and affect the brain. Bromoform has been found in at least 140 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA). Dibromochloromethane has been found in at least 174 NPL sites.

What are bromoform and dibromochloromethane?

Bromoform and dibromochloromethane are colorless to yellow, heavy, nonflammable, liquids with a sweet odor. Small amounts are formed naturally by plants in the ocean. They are somewhat soluble in water and readily evaporate into the air. Most of the bromoform and dibromochloromethane that enters the environment is formed as byproducts when chlorine is added to drinking water to kill bacteria.

Only small quantities of bromoform and dibromochloromethane currently are produced in the United States. These chemicals were used in the past as solvents and flame retardants, or to make other chemicals, but now they are used mainly as laboratory reagents.

What happens to bromoform and dibromochloromethane when they enter the environment?

- When released to air, bromoform and dibromochloromethane are slowly broken down by reactions with other chemicals and sunlight or can be removed by rain.
- In water, these chemicals will evaporate to the air and/or be broken down slowly by bacteria.
- When released to soil, most will evaporate to the air, some will be broken down by bacteria, and some may filter into the groundwater.
- Bromoform and dibromomethane do not build up in the food chain.

How might I be exposed to bromoform and dibromochloromethane?

- The most likely way people are exposed to bromoform and dibromochloromethane is by drinking chlorinated water.
- You may breathe vapors released from chlorinated water in a swimming pool or during showering and bathing.
- Very small amounts of bromoform and dibromochloromethane may enter your body directly through your skin while bathing or swimming.
- People that live near a waste site containing bromoform or dibromochloromethane could be exposed by drinking contaminated groundwater or breathing vapors released to the air.
- Exposure could occur by breathing bromoform and dibromochloromethane in the air in or near a laboratory or factory that makes or uses these chemicals; however, this is unlikely for most people.

How can bromoform and dibromochloromethane affect my health?

Eating or breathing a large amount of bromoform slows down the normal brain activities and causes sleepiness; this tends to go away within a day. Exposure to very high amounts may cause unconsciousness and even death. No studies are available about health effects in people exposed to dibromochloromethane.

Animals exposed to high amounts of bromoform or dibromochloromethane developed liver and kidney injuries. Exposure to low levels of bromoform or

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

dibromochloromethane do not appear to seriously affect the brain, liver, or kidneys. We do not know if bromoform or dibromochloromethane affect fertility in humans, but studies in animals suggest that the risk of doing so is low.

How likely are bromoform and dibromochloromethane to cause cancer?

There is no conclusive evidence that bromoform or dibromochloromethane cause cancer in humans because no cancer studies of humans exposed exclusively to these chemicals are available. Studies in animals indicate that long-term intake of either bromoform or dibromochloromethane can cause liver and kidney cancer.

The International Agency for Research on Cancer (IARC) concluded that bromoform and dibromochloromethane are not classifiable as to human carcinogenicity. The EPA classified bromoform as a probable human carcinogen and dibromochloromethane as a possible human carcinogen.

How can bromoform and dibromochloromethane affect children?

The only information regarding effects of bromoform on the health of children is that from the early 1900s when this chemical was used as a sedative to treat children with whooping cough. In some cases of overdosing with extremely high doses, children appeared drowsy, then lifeless, just before dying. We do not know whether children are more susceptible to the effects of bromoform and dibromochloromethane than adults.

How can families reduce the risks of exposure to bromoform and dibromochloromethane?

- Families can reduce their exposure to bromoform and dibromochloromethane from tap water by installing commercially available filter systems at home.
- While bromoform is no longer used as a medicine, keeping children away from, or supervising children with, chemicals brought into the home, will reduce the potential for accidental exposures.

- Families can reduce their exposure by taking shorter baths or showers in water in which these chemicals are present and opening bathroom windows or using ceiling ventilation fans whenever possible.

Is there a medical test to determine whether I've been exposed to bromoform and dibromochloromethane?

Tests are available to measure levels of these chemicals and their breakdown products in samples of your blood, breath, or fat. These tests are not routinely available in a doctor's office because they require special equipment. Because bromoform and dibromochloromethane are eliminated from the body fairly quickly, these tests are only effective in detecting recent exposures (within 1 or 2 days at the most).

Has the federal government made recommendations to protect human health?

The EPA recommends that drinking water contain no more than 0.7 parts per million (0.7 ppm) of bromoform and 0.7 ppm of dibromochloromethane.

The Occupational Safety and Health Administration (OSHA) set a limit of 0.5 ppm for the level of bromoform in workplace air during an 8-hour workday, 40-hour work week. Because dibromochloromethane has such a limited use, OSHA has not set limits of exposure for workplace air.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about chloroform. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to chloroform can occur when breathing contaminated air or when drinking or touching the substance or water containing it. Breathing chloroform can cause dizziness, fatigue, and headaches. Breathing chloroform or ingesting chloroform over long periods of time may damage your liver and kidneys. It can cause sores if large amounts touch your skin. This substance has been found in at least 717 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is chloroform?

(Pronounced klôr'ə-fôrm')

Chloroform is a colorless liquid with a pleasant, nonirritating odor and a slightly sweet taste. It will burn only when it reaches very high temperatures.

In the past, chloroform was used as an inhaled anesthetic during surgery, but it isn't used that way today. Today, chloroform is used to make other chemicals and can also be formed in small amounts when chlorine is added to water.

Other names for chloroform are trichloromethane and methyl trichloride.

What happens to chloroform when it enters the environment?

- Chloroform evaporates easily into the air.
- Most of the chloroform in air breaks down eventually, but it is a slow process.
- The breakdown products in air include phosgene and hydrogen chloride, which are both toxic.
- It doesn't stick to soil very well and can travel through soil to groundwater.

- Chloroform dissolves easily in water and some of it may break down to other chemicals.
- Chloroform lasts a long time in groundwater.
- Chloroform doesn't appear to build up in great amounts in plants and animals.

How might I be exposed to chloroform?

- Drinking water or beverages made using water containing chloroform.
- Breathing indoor or outdoor air containing it, especially in the workplace.
- Eating food that contains it.
- Skin contact with chloroform or water that contains it, such as in swimming pools.

How can chloroform affect my health?

Breathing about 900 parts of chloroform per million parts air (900 ppm) for a short time can cause dizziness, fatigue, and headache. Breathing air, eating food, or drinking water containing high levels of chloroform for long periods of time may damage your liver and kidneys. Large amounts of chloroform can cause sores when chloroform touches your skin.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

It isn't known whether chloroform causes reproductive effects or birth defects in people.

Animal studies have shown that miscarriages occurred in rats and mice that breathed air containing 30 to 300 ppm chloroform during pregnancy and also in rats that ate chloroform during pregnancy. Offspring of rats and mice that breathed chloroform during pregnancy had birth defects. Abnormal sperm were found in mice that breathed air containing 400 ppm chloroform for a few days.

How likely is chloroform to cause cancer?

The Department of Health and Human Services (DHHS) has determined that chloroform may reasonably be anticipated to be a carcinogen.

Rats and mice that ate food or drank water with chloroform developed cancer of the liver and kidneys.

Is there a medical test to show whether I've been exposed to chloroform?

Although the amounts of chloroform in the air that you exhale and in blood, urine, and body tissues can be measured, there is no reliable test to determine how much chloroform you have been exposed to or whether you will experience any harmful effects.

The measurement of chloroform in body fluids and tissues may help to determine if you have come into contact with large amounts of chloroform, but these tests are useful for only a short time after you are exposed. Chloroform in your body might also indicate that you have come into contact with other chemicals.

Has the federal government made recommendations to protect human health?

The EPA drinking water limit for total trihalomethanes, a class of chemicals that includes chloroform, is 100 micrograms per liter of water (100 µg/L).

The EPA requires that spills or accidental releases of 10 pounds or more of chloroform into the environment be reported to the EPA.

The Occupational Safety and Health Administration (OSHA) has set the maximum allowable concentration of chloroform in workroom air during an 8-hour workday in a 40-hour workweek at 50 ppm.

Glossary

Carcinogenicity: A substance with the ability to cause cancer.

CAS: Chemical Abstracts Service.

Ingesting: Taking food or drink into your body.

Microgram (µg): One millionth of a gram.

Miscarriage: Pregnancy loss.

ppm: Parts per million.

You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet was created from information obtained from the United States Environmental Protection Agency (USEPA) Total Coliform Rule, found at <http://www.epa.gov/safewater/disinfection/tcr/index.html>. This fact sheet answers the most frequently asked health questions (FAQs) about coliforms and fecal coliforms. It is important you understand this information because these substances may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: Total coliforms and fecal coliforms are groups of bacteria used as indicators of possible sewage contamination because they are commonly found in human and animal feces. Although they are generally not harmful themselves, they indicate the possible presence of pathogenic (disease-causing) bacteria, viruses, and protozoans that also live in human and animal digestive systems. Therefore, their presence in well water suggests that pathogenic microorganisms might also be present and that drinking well water might be a health risk. Sources of fecal contamination to well water includes septic systems, domestic and wild animal manure, and storm runoff.

What are total coliforms/fecal coliforms?

Total coliforms and fecal coliforms are a group of closely related bacteria that are usually free-living in the environment, but that are also present in water contaminated with human and animal feces. In general, coliform counts give an overall indication of the sanitary condition of a water supply. Fecal coliforms are bacteria found in feces, and are a subgroup of coliforms. Fecal coliforms normally reside in the intestinal tract of warm-blooded animals. The fecal coliform group includes both pathogen (disease-causing) and nonpathogenic bacteria. The presence of fecal coliforms in drinking water indicates that disease-causing organisms may be present.

Coliform contamination can occur when increased run-off enters the drinking water source (for example, following heavy rains). It can also happen due to a break in the water distribution system (pipes), or failure of a water treatment process.

What happens to coliforms/fecal coliforms when they enter the environment?

- Coliforms are free-living bacteria that are normally found in the environment.
- Coliforms are short-lived in the environment, outside of a warm-blooded host.

How might I be exposed to total coliforms/fecal coliforms?

- Ingesting coliforms in drinking water
- Ingesting fecal contaminated foodstuffs

How can coliforms/fecal coliforms affect my health?

Most coliform bacteria do not cause illness. However, their presence in a water system is a public health concern because of the potential for disease-causing strains of bacteria, viruses, and protozoa to also be present. Symptoms from water-borne illness may include diarrhea, cramps, nausea, headaches, jaundice, or fatigue. Symptoms may appear as early as a few hours to several days after infection and may last more than two weeks.

How can coliforms/fecal coliforms affect children?

Children experience the same health effect as adults following exposure. However, they may experience more severe symptoms due to immature immune systems and due to their increased susceptibility to dehydration.

How can families reduce the risks of exposure to coliforms/fecal coliforms?

- Drinking water should be periodically tested for total coliforms/fecal coliforms.
- If your drinking water has elevated levels of total coliforms or fecal coliforms you should use cleaner sources of water.

Is there a medical test to determine whether I've been exposed to coliforms/fecal coliforms?

Coliforms and fecal coliforms are typically present in the digestive system, however a stool sample may reveal an elevated level of a pathogenic strain, or the presence of a less common strain that may be associated with illness.

Has the federal government made recommendations to protect human health?

The USEPA has set and enforceable standard called a maximum contaminant level (MCL) for coliforms and fecal coliforms of zero colony-forming units (CFUs) per 100 milliliters water. The USEPA believes that any detection of coliforms or fecal coliforms in drinking water could potentially be associated with human illness.

Where Can I Get More Information? More information on the adverse effects of fecal coliforms/total coliforms can be obtained from your community or state health or environmental quality department.

This fact sheet answers the most frequently asked health questions (FAQs) about di(2-ethylhexyl) phthalate (DEHP). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Di(2-ethylhexyl) phthalate (DEHP) is found in many plastics. Exposure to DEHP is generally very low. Increased exposures may come from intravenous fluids delivered through plastic tubing, and from ingesting contaminated foods or water. DEHP is not toxic at the low levels usually present in the environment. In animals, high levels of DEHP damaged the liver and kidney and affected the ability to reproduce. DEHP has been found in at least 733 of the 1,613 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is di(2-ethylhexyl) phthalate?

Di(2-ethylhexyl) phthalate (DEHP) is a manufactured chemical that is commonly added to plastics to make them flexible. DEHP is a colorless liquid with almost no odor.

DEHP is present in plastic products such as wall coverings, tablecloths, floor tiles, furniture upholstery, shower curtains, garden hoses, swimming pool liners, rainwear, baby pants, dolls, some toys, shoes, automobile upholstery and tops, packaging film and sheets, sheathing for wire and cable, medical tubing, and blood storage bags.

What happens to DEHP when it enters the environment?

- DEHP is everywhere in the environment because of its use in plastics, but it does not evaporate easily or dissolve in water easily.
- DEHP can be released in small amounts to indoor air from plastic materials, coatings, and flooring.
- It dissolves faster in water if gas, oil, or paint removers are present.
- It attaches strongly to soil particles.
- DEHP in soil or water can be broken down by microorganisms into harmless compounds.

- DEHP does not break down easily when it is deep in the soil or at the bottom of lakes or rivers.
- It is in plants, fish, and other animals, but animals high on the food chain are able to break down DEHP, so tissue levels are usually low.

How might I be exposed to DEHP?

DEHP is usually present at very low levels in:

- Medical products packaged in plastic such as blood products.
- Some foods packaged in plastics, especially fatty foods like milk products, fish or seafood, and oils.
- Well water near waste sites.
- Workplace air or indoor air where DEHP is released, but usually not at levels of concern.
- Fluids from plastic intravenous tubing if used extensively as for kidney dialysis.

How can DEHP affect my health?

At the levels found in the environment, DEHP is not expected to cause harmful health effects in humans. Most of what we know about the health effects of DEHP comes from studies of rats and mice given high amounts of DEHP.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Harmful effects in animals generally occurred only with high amounts of DEHP or with prolonged exposures. Moreover, absorption and breakdown of DEHP in humans is different than in rats or mice, so the effects seen in rats and mice may not occur in humans.

Rats that breathed DEHP in the air showed no serious harmful effects. Their lifespan and ability to reproduce were not affected.

Brief oral exposure to very high levels of DEHP damaged sperm in mice. Although the effect reversed when exposure ceased, sexual maturity was delayed in the animals.

High amounts of DEHP damaged the liver of rats and mice. Whether or not DEHP contributes to human kidney damage is unclear.

Skin contact with products containing DEHP will probably cause no harmful effects because it cannot be taken up easily through the skin.

How likely is DEHP to cause cancer?

The Department of Health and Human Services (DHHS) has determined that DEHP may reasonably be anticipated to be a human carcinogen. The EPA has determined that DEHP is a probable human carcinogen. These determinations were based entirely on liver cancer in rats and mice. The International Agency for Research on Cancer (IARC) has stated that DEHP cannot be classified as to its carcinogenicity to humans.

How can DEHP affect children?

Children can be exposed to DEHP in the same manner as adults. In addition, small children can be exposed by sucking on or skin contact with plastic toys and pacifiers that contain DEHP, but there is no conclusive evidence of adverse health effects after such exposures. Nonetheless, because of concern for children's health, many toy

manufacturers have discontinued use of DEHP in their products. In pregnant rats and mice exposed to high amounts of DEHP, researchers observed birth defects and fetal deaths.

How can families reduce the risk of exposure to DEHP?

- It is almost impossible to completely avoid contact with some DEHP because it is commonly found in plastics.
- Prevent babies and small children from chewing on plastic objects not designed for that purpose.

Is there a medical test to show whether I've been exposed to DEHP?

There is a test available that measures a breakdown product of DEHP called mono(2-ethylhexyl) phthalate (MEHP) in your urine or blood. This test can only detect recent exposure because DEHP is rapidly broken down and eliminated from your body. This test is not routinely available at the doctor's office because it requires special equipment.

Has the federal government made recommendations to protect human health?

The EPA limits the amount of DEHP that may be present in drinking water to 6 parts of DEHP per billion parts of water (6 ppb).

The Occupational Safety and Health Administration (OSHA) sets a maximum average of 5 milligrams of DEHP per cubic meter of air (5 mg/m³) in the workplace during an 8-hour shift. The short-term (15-minute) exposure limit is 10 mg/m³.

This fact sheet answers the most frequently asked health questions (FAQs) about tetrachloroethylene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Tetrachloroethylene is a manufactured chemical used for dry cleaning and metal degreasing. Exposure to very high concentrations of tetrachloroethylene can cause dizziness, headaches, sleepiness, confusion, nausea, difficulty in speaking and walking, unconsciousness, and death. Tetrachloroethylene has been found in at least 771 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is tetrachloroethylene?

(Pronounced tět'rə-klôr' 0-ěth'ə-lēn')

Tetrachloroethylene is a manufactured chemical that is widely used for dry cleaning of fabrics and for metal-degreasing. It is also used to make other chemicals and is used in some consumer products.

Other names for tetrachloroethylene include perchloroethylene, PCE, and tetrachloroethene. It is a nonflammable liquid at room temperature. It evaporates easily into the air and has a sharp, sweet odor. Most people can smell tetrachloroethylene when it is present in the air at a level of 1 part tetrachloroethylene per million parts of air (1 ppm) or more, although some can smell it at even lower levels.

What happens to tetrachloroethylene when it enters the environment?

- Much of the tetrachloroethylene that gets into water or soil evaporates into the air.
- Microorganisms can break down some of the tetrachloroethylene in soil or underground water.
- In the air, it is broken down by sunlight into other chemicals or brought back to the soil and water by rain.
- It does not appear to collect in fish or other animals that live in water.

How might I be exposed to tetrachloroethylene?

- When you bring clothes from the dry cleaners, they will release small amounts of tetrachloroethylene into the air.
- When you drink water containing tetrachloroethylene, you are exposed to it.

How can tetrachloroethylene affect my health?

High concentrations of tetrachloroethylene (particularly in closed, poorly ventilated areas) can cause dizziness, headache, sleepiness, confusion, nausea, difficulty in speaking and walking, unconsciousness, and death.

Irritation may result from repeated or extended skin contact with it. These symptoms occur almost entirely in work (or hobby) environments when people have been accidentally exposed to high concentrations or have intentionally used tetrachloroethylene to get a "high."

In industry, most workers are exposed to levels lower than those causing obvious nervous system effects. The health effects of breathing in air or drinking water with low levels of tetrachloroethylene are not known.

Results from some studies suggest that women who work in dry cleaning industries where exposures to tetrachloroethyl-

ToxFAQs Internet home page via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

ene can be quite high may have more menstrual problems and spontaneous abortions than women who are not exposed. However, it is not known if tetrachloroethylene was responsible for these problems because other possible causes were not considered.

Results of animal studies, conducted with amounts much higher than those that most people are exposed to, show that tetrachloroethylene can cause liver and kidney damage. Exposure to very high levels of tetrachloroethylene can be toxic to the unborn pups of pregnant rats and mice. Changes in behavior were observed in the offspring of rats that breathed high levels of the chemical while they were pregnant.

How likely is tetrachloroethylene to cause cancer?

The Department of Health and Human Services (DHHS) has determined that tetrachloroethylene may reasonably be anticipated to be a carcinogen. Tetrachloroethylene has been shown to cause liver tumors in mice and kidney tumors in male rats.

Is there a medical test to show whether I've been exposed to tetrachloroethylene?

One way of testing for tetrachloroethylene exposure is to measure the amount of the chemical in the breath, much the same way breath-alcohol measurements are used to determine the amount of alcohol in the blood.

Because it is stored in the body's fat and slowly released into the bloodstream, tetrachloroethylene can be detected in the breath for weeks following a heavy exposure.

Tetrachloroethylene and trichloroacetic acid (TCA), a breakdown product of tetrachloroethylene, can be detected in the blood. These tests are relatively simple to perform. These tests aren't available at most doctors' offices, but can be per-

formed at special laboratories that have the right equipment.

Because exposure to other chemicals can produce the same breakdown products in the urine and blood, the tests for breakdown products cannot determine if you have been exposed to tetrachloroethylene or the other chemicals.

Has the federal government made recommendations to protect human health?

The EPA maximum contaminant level for the amount of tetrachloroethylene that can be in drinking water is 0.005 milligrams tetrachloroethylene per liter of water (0.005 mg/L).

The Occupational Safety and Health Administration (OSHA) has set a limit of 100 ppm for an 8-hour workday over a 40-hour workweek.

The National Institute for Occupational Safety and Health (NIOSH) recommends that tetrachloroethylene be handled as a potential carcinogen and recommends that levels in workplace air should be as low as possible.

Glossary

Carcinogen: A substance with the ability to cause cancer.

CAS: Chemical Abstracts Service.

Milligram (mg): One thousandth of a gram.

Nonflammable: Will not burn.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about chlorinated dibenzo-p-dioxins (CDDs). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to chlorinated dibenzo-p-dioxins (CDDs) (75 chemicals) occurs mainly from eating food that contains the chemicals. One chemical in this group, 2,3,7,8-tetrachlorodibenzo-p-dioxin or 2,3,7,8-TCDD, has been shown to be very toxic in animal studies. It causes effects on the skin and may cause cancer in people. This chemical has been found in at least 91 of 1,467 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What are CDDs?

CDDs are a family of 75 chemically related compounds commonly known as chlorinated dioxins. One of these compounds is called 2,3,7,8-TCDD. It is one of the most toxic of the CDDs and is the one most studied.

In the pure form, CDDs are crystals or colorless solids. CDDs enter the environment as mixtures containing a number of individual components. 2,3,7,8-TCDD is odorless and the odors of the other CDDs are not known.

CDDs are not intentionally manufactured by industry except for research purposes. They (mainly 2,3,7,8-TCDD) may be formed during the chlorine bleaching process at pulp and paper mills. CDDs are also formed during chlorination by waste and drinking water treatment plants. They can occur as contaminants in the manufacture of certain organic chemicals. CDDs are released into the air in emissions from municipal solid waste and industrial incinerators.

What happens to CDDs when they enter the environment?

- When released into the air, some CDDs may be transported long distances, even around the globe.

- When released in waste waters, some CDDs are broken down by sunlight, some evaporate to air, but most attach to soil and settle to the bottom sediment in water.
- CDD concentrations may build up in the food chain, resulting in measurable levels in animals.

How might I be exposed to CDDs?

- Eating food, primarily meat, dairy products, and fish, makes up more than 90% of the intake of CDDs for the general population.
- Breathing low levels in air and drinking low levels in water.
- Skin contact with certain pesticides and herbicides.
- Living near an uncontrolled hazardous waste site containing CDDs or incinerators releasing CDDs.
- Working in industries involved in producing certain pesticides containing CDDs as impurities, working at paper and pulp mills, or operating incinerators.

How can CDDs affect my health?

The most noted health effect in people exposed to large amounts of 2,3,7,8-TCDD is chloracne. Chloracne is a severe skin disease with acne-like lesions that occur mainly on the face and upper body. Other skin effects noted in people exposed to high doses of 2,3,7,8-TCDD include skin rashes, dis-

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

coloration, and excessive body hair. Changes in blood and urine that may indicate liver damage also are seen in people. Exposure to high concentrations of CDDs may induce long-term alterations in glucose metabolism and subtle changes in hormonal levels.

In certain animal species, 2,3,7,8-TCDD is especially harmful and can cause death after a single exposure. Exposure to lower levels can cause a variety of effects in animals, such as weight loss, liver damage, and disruption of the endocrine system. In many species of animals, 2,3,7,8-TCDD weakens the immune system and causes a decrease in the system's ability to fight bacteria and viruses. In other animal studies, exposure to 2,3,7,8-TCDD has caused reproductive damage and birth defects. Some animal species exposed to CDDs during pregnancy had miscarriages and the offspring of animals exposed to 2,3,7,8-TCDD during pregnancy often had severe birth defects including skeletal deformities, kidney defects, and weakened immune responses.

How likely are CDDs to cause cancer?

Several studies suggest that exposure to 2,3,7,8-TCDD increases the risk of several types of cancer in people. Animal studies have also shown an increased risk of cancer from exposure to 2,3,7,8-TCDD.

The World Health Organization (WHO) has determined that 2,3,7,8-TCDD is a human carcinogen.

The Department of Health and Human Services (DHHS) has determined that 2,3,7,8-TCDD may reasonably be anticipated to cause cancer.

How can CDDs affect children?

Very few studies have looked at the effects of CDDs on children. Chloracne has been seen in children exposed to high levels of CDDs. We don't know if CDDs affect the ability of people to have children or if it causes birth defects, but given the effects observed in animal studies, this cannot be ruled out.

How can families reduce the risk of exposure to CDDs?

- Children should avoid playing in soils near uncontrolled hazardous waste sites.
- Discourage children from eating dirt or putting toys or other objects in their mouths.
- Everyone should wash hands frequently if playing or working near uncontrolled hazardous waste sites.
- For new mothers and young children, restrict eating foods from the proximity of uncontrolled sites with known CDDs.

Is there a medical test to show whether I've been exposed to CDDs?

Tests are available to measure CDD levels in body fat, blood, and breast milk, but these tests are not routinely available. Most people have low levels of CDDs in their body fat and blood, and levels considerably above these levels indicate past exposure to above-normal levels of 2,3,7,8-TCDD. Although CDDs stay in body fat for a long time, tests cannot be used to determine when exposure occurred.

Has the federal government made recommendations to protect human health?

The EPA has set a limit of 0.00003 micrograms of 2,3,7,8-TCDD per liter of drinking water (0.00003 µg/L). Discharges, spills, or accidental releases of 1 pound or more of 2,3,7,8-TCDD must be reported to EPA. The Food and Drug Administration (FDA) recommends against eating fish and shellfish with levels of 2,3,7,8-TCDD greater than 50 parts per trillion (50 ppt).

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html> ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet was created from information presented in the Agency for Toxic Substances and Disease Registry (ATSDR) Case Studies in Environmental Medicine Course (ATSDR, 2007). This fact sheet answers the most frequently asked health questions (FAQs) about nitrate and nitrite. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: The widespread use of nitrate fertilizers has increased the risk of well water contamination in rural areas. Shallow, rural domestic wells are those most likely to be contaminated with nitrates, especially in agricultural areas where nitrogen based fertilizers are in use. Other nitrate sources in well water include seepage from septic sewer systems, or other contaminants. The conversion of nitrates to nitrites in the body significantly enhances nitrates' toxicity. Infants younger than four months are at particular risk of nitrate toxicity from contaminated well water. Parents that use water to make formula for infants should be especially careful.

What are nitrates and nitrites?

Nitrate (NO_3^-) and nitrite (NO_2^-) are naturally occurring inorganic ions that are part of the nitrogen cycle. Microbial action in soil or water decomposes wastes containing organic nitrogen into ammonia, which is then oxidized to nitrite and nitrate.

Because nitrite is easily oxidized to nitrate, nitrate is the compound predominantly found in groundwater and surface water.

Contamination with nitrogen-containing fertilizers (e.g. potassium nitrate and ammonium nitrate), or animal or human organic wastes, can raise the concentration of nitrate in water.

What happens to nitrate/nitrite when it enters the environment?

- Nitrate-containing compounds in the soil are generally soluble and readily migrate with groundwater.
- Microbial action in soil or water decomposes wastes containing organic nitrogen into ammonia, which is then oxidized to nitrite and nitrate.

How might I be exposed to nitrate/nitrite?

- Ingesting nitrate and nitrite in well water used for drinking water
- Infants ingesting formula made with water containing nitrate or nitrite.

- Ingesting contaminated foodstuffs
- Ingesting prepared baby foods and sausage preserved with nitrates and nitrites.
- Ingesting certain medications and breathing volatile nitrite inhalants.

How can nitrate/nitrite affect my health?

Ingesting high levels of nitrate/nitrite can cause methemoglobinemia. Methemoglobinemia is a disorder characterized by the presence of a higher than normal level of methemoglobin in the blood. Methemoglobin is a form of hemoglobin that does not bind oxygen. When its concentration is elevated in red blood cells, anemia and tissue hypoxia can occur.

How likely is nitrate/nitrite to cause cancer?

Nitrate and nitrite have not undergone an evaluation of carcinogenic potential by the U.S. Environmental Protection Agency (USEPA).

How can nitrate/nitrite affect children?

As with adults, ingesting high levels of nitrate/nitrite can cause methemoglobinemia. Infants under the age of four months are at higher risk due to their reduced ability to convert methemoglobin back to hemoglobin. In addition, the high pH of the infant gastrointestinal system favors the growth of bacteria that reduce nitrate to nitrite, which is responsible for creation of methemoglobin.

How can families reduce the risks of exposure to nitrate/nitrite?

- Well water should be periodically tested for nitrate/nitrite.
- If your drinking water has elevated levels of nitrate/nitrate you should use cleaner sources of water.
- If your drinking water has elevated levels of nitrate/nitrate you should not use it to make baby formula.

Is there a medical test to determine whether I've been exposed to nitrate/nitrite?

The most useful diagnostic tests measure the methemoglobin concentration in blood, which is an indicator of nitrate/nitrite toxicity. Tests include both a visual observation of blood, which is chocolate-brown in appearance when there is a high

concentration of methemoglobin, and measurement of the oxygen carrying capacity of blood, which is reduced when a high level of methemoglobin is present.

Has the federal government made recommendations to protect human health?

The USEPA has set an enforceable standard called a maximum contaminant level (MCL) for nitrates at 10 parts per million (ppm), and for nitrites at 1 ppm. The USEPA believes that exposure below this level is not expected to cause health problems.

The Joint Expert Committee on Food Additives (JECFA) of the Food and Agriculture Organization of the United Nations/World Health Organization and the European Commission's Scientific Committee on Food have set an acceptable daily intake (ADI) for nitrate of 0 – 3.7 mg nitrate ion/kg body weight.

This fact sheet answers the most frequently asked health questions (FAQs) about uranium. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Uranium is a naturally occurring chemical substance that is mildly radioactive. Everyone is exposed to low amounts of uranium through food, air, and water. Exposure to high levels of uranium can cause kidney disease. It is not known to cause cancer, but can decay into other radioactive materials that may. Uranium above background levels has been found in at least 54 of the 1,517 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is uranium?

(Pronounced yoo-rā'nē-əm)

Uranium is a common naturally occurring and radioactive substance. It is a normal part of rocks, soil, air, and water, and it occurs in nature in the form of minerals - but never as a metal. Uranium metal is silver-colored with a gray surface and is nearly as strong as steel. Natural uranium is a mixture of three types or isotopes called U-234 (²³⁴U), U-235 (²³⁵U), and U-238 (²³⁸U). All three are the same chemical, but they have different radioactive properties.

Typical concentrations in soil are a few parts per million (ppm). Some rocks contain high enough mineral concentrations of uranium to be mined. The rocks are taken to a chemical plant where the uranium is taken out and made into uranium chemicals or metal. The remaining sand is called mill tailings. Tailings are rich in the chemicals and radioactive materials that were not removed, such as radium and thorium.

One of the radioactive properties of uranium is half-life, or the time it takes for half of the isotope to give off its radiation and change into another substance. The half-lives are very long (around 200,000 years for ²³⁴U, 700 million years for ²³⁵U, and 5 billion years for ²³⁸U). This is why uranium still exists in nature and has not all decayed away.

The isotope ²³⁵U is useful as a fuel in power plants and weapons. To make fuel, natural uranium is separated into two portions. The fuel portion has more ²³⁵U than normal and is called enriched uranium. The leftover portion with less ²³⁵U than normal is called depleted uranium, or DU. Natural, de-

pleted, and enriched uranium are chemically identical. DU is the least radioactive and enriched uranium is the most.

What happens to uranium when it enters the environment?

- Uranium is already naturally present throughout the environment. Human activities, wind, streams, and volcanoes can move the uranium around and change the levels that you are exposed to.
- Uranium is found in soil where it may stay for billions of years.
- It exists as dust in the air and the dust settles onto surface water, soil, and plants.
- Uranium enters water by dissolving soil, eroding soil and rocks, or in releases from processing plants. Larger particles settle into the bottom of lakes, rivers, and ponds and join uranium that is there naturally.
- Some plants may absorb uranium or it may stick to the root surface.

How might I be exposed to uranium?

- Breathing air or drinking water in a place that has higher than background levels of uranium.
- Eating food grown in areas with higher than background levels of uranium.
- Working in factories that process uranium or with phosphate fertilizers, or living near any type of mine.
- Living near a coal-fired power plant.

How can uranium affect my health?

All uranium mixtures (natural, depleted, and enriched) have the same chemical effect on your body. Large amounts of uranium can react with the tissues in your body and damage

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

your kidneys. The radiation damage from exposure to high levels of natural or depleted uranium are not known to cause cancer (see next section).

How likely is uranium to cause cancer?

Humans and animals exposed to high levels of uranium did not have higher cancer rates. The Committee on the Biological Effects of Ionizing Radiation (BEIR IV) reported that eating food or drinking water that has normal amounts of uranium will most likely not cause cancer.

Uranium can decay into other radioactive substances, such as radium, which can cause cancer if you are exposed to enough of them for a long enough period of time. Studies have reported lung and other cancers in uranium miners; however, the miners also smoked and were exposed to other substances that cause cancer, such as radon and silica dust.

How can uranium affect children?

Like adults, children are exposed to small amounts of uranium in air, food, and drinking water. If children were exposed to very large amounts of uranium, it is possible that they might have kidney damage like that seen in adults. We do not know whether children differ from adults in their susceptibility to the health effects of uranium exposure.

It is not known if exposure to uranium can affect the developing human fetus. In laboratory animals, high doses of uranium in drinking water resulted in birth defects and an increase in fetal deaths. Measurements of uranium have not been made in pregnant women, so we do not know if uranium can cross the placenta and enter the fetus. In an experiment with pregnant animals, only a small amount of the injected uranium reached the fetus.

How can families reduce the risk of exposure to uranium?

If your doctor finds that you have been exposed to significant amounts of uranium, ask whether your children might also be exposed. Your doctor might need to ask your state health department to investigate.

It is possible that higher-than-normal levels of uranium may be in the soil at a hazardous waste site. If you live near such a hazardous waste site, you should prevent your children from eating dirt and make sure that they wash their hands frequently and before eating. You should also wash fruits and vegetables grown in that soil well, and consider discarding the outside portion of root vegetables.

Is there a medical test to show whether I've been exposed to uranium?

Uranium is in your normal diet, so there will always be some level of uranium in all parts of your body. Uranium is normally measured in a sample of urine collected and sent to a laboratory. Blood, feces, and tissue samples are rarely used. Because most uranium leaves the body within a few days, higher than normal amounts in your urine shows whether you have been exposed to larger-than-normal amounts within the last week or so. Some highly sensitive radiation methods can measure uranium levels for a long time after you take in a large amount. Also, some radiation equipment can tell if uranium is on your skin.

Has the federal government made recommendations to protect human health?

The EPA requires that spills or accidental releases of uranium waste into the environment containing 0.1 curies or more of radioactivity must be reported to the EPA.

The EPA is currently working to develop an appropriate drinking water limit for uranium based on a broad range of human and animal health studies.

The Occupational Safety and Health Administration has set occupational exposure limits for uranium in breathing air over an 8-hour workday, 40-hour workweek. The limits are 0.05 milligrams per cubic meter (0.05 mg/m³) for soluble uranium dust and 0.25 mg/m³ for insoluble uranium dust.

This fact sheet answers the most frequently asked health questions (FAQs) about zinc. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Zinc is a naturally occurring element. Exposure to high levels of zinc occurs mostly from eating food, drinking water, or breathing workplace air that is contaminated. Low levels of zinc are essential for maintaining good health. Exposure to large amounts of zinc can be harmful. It can cause stomach cramps, anemia, and changes in cholesterol levels. Zinc has been found in at least 985 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is zinc?

Zinc is one of the most common elements in the earth's crust. It is found in air, soil, and water, and is present in all foods. Pure zinc is a bluish-white shiny metal.

Zinc has many commercial uses as coatings to prevent rust, in dry cell batteries, and mixed with other metals to make alloys like brass, and bronze. A zinc and copper alloy is used to make pennies in the United States.

Zinc combines with other elements to form zinc compounds. Common zinc compounds found at hazardous waste sites include zinc chloride, zinc oxide, zinc sulfate, and zinc sulfide. Zinc compounds are widely used in industry to make paint, rubber, dyes, wood preservatives, and ointments.

What happens to zinc when it enters the environment?

- Some is released into the environment by natural processes, but most comes from human activities like mining, steel production, coal burning, and burning of waste.
- It attaches to soil, sediments, and dust particles in the air.
- Rain and snow remove zinc dust particles from the air.
- Depending on the type of soil, some zinc compounds can move into the groundwater and into lakes, streams, and rivers.
- Most of the zinc in soil stays bound to soil particles and

does not dissolve in water.

- It builds up in fish and other organisms, but it does not build up in plants.

How might I be exposed to zinc?

- Ingesting small amounts present in your food and water.
- Drinking contaminated water or a beverage that has been stored in metal containers or flows through pipes that have been coated with zinc to resist rust.
- Eating too many dietary supplements that contain zinc.
- Working on any of the following jobs: construction, painting, automobile mechanics, mining, smelting, and welding; manufacture of brass, bronze, or other zinc-containing alloys; manufacture of galvanized metals; and manufacture of machine parts, rubber, paint, linoleum, oilcloths, batteries, some kind of glass, ceramics, and dyes.

How can zinc affect my health?

Zinc is an essential element in our diet. Too little zinc can cause problems, but too much zinc is also harmful.

Harmful effects generally begin at levels 10-15 times higher than the amount needed for good health. Large doses taken by mouth even for a short time can cause stomach cramps, nausea, and vomiting. Taken longer, it can cause anemia and decrease the levels of your good cholesterol. We do not know if high levels of zinc affect reproduction in humans. Rats that were fed large amounts of zinc became infertile.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Inhaling large amounts of zinc (as dusts or fumes) can cause a specific short-term disease called metal fume fever. We do not know the long-term effects of breathing high levels of zinc.

Putting low levels of zinc acetate and zinc chloride on the skin of rabbits, guinea pigs, and mice caused skin irritation. Skin irritation will probably occur in people.

How likely is zinc to cause cancer?

The Department of Health and Human Services (DHHS) and the International Agency for Research on Cancer (IARC) have not classified zinc for carcinogenicity. Based on incomplete information from human and animal studies, the EPA has determined that zinc is not classifiable as to its human carcinogenicity.

How can zinc affect children?

Zinc is essential for proper growth and development of young children. It is likely that children exposed to very high levels of zinc will have similar effects as adults. We do not know whether children are more susceptible to the effects of excessive intake of zinc than the adults.

We do not know if excess zinc can cause developmental effects in humans. Animal studies have found decreased weight in the offspring of animals that ingested very high amounts of zinc.

How can families reduce the risks of exposure to zinc?

- Children living near waste sites that contain zinc may be exposed to higher levels of zinc through breathing contaminated air, drinking contaminated drinking water, touching or eating contaminated soil.
- Discourage your children from eating soil or putting their hands in their mouths and teach them to wash their hands frequently and before eating.
- If you use medicines or vitamin supplements containing

zinc, make sure you use them appropriately and keep them out of the reach of children.

Is there a medical test to determine whether I've been exposed to zinc?

There are tests available to measure zinc in your blood, urine, hair, saliva, and feces. These tests are not usually done in the doctor's office because they require special equipment. High levels of zinc in the feces can mean high recent zinc exposure. High levels of zinc in the blood can mean high zinc consumption and/or high exposure. Tests to measure zinc in hair may provide information on long-term zinc exposure; however, the relationship between levels in your hair and the amount of zinc you were exposed to is not clear.

Has the federal government made recommendations to protect human health?

The EPA recommends that drinking water should contain no more than 5 milligrams per liter of water (5 mg/L) because of taste. The EPA requires that any release of 1,000 pounds (or in some cases 5,000 pounds) into the environment be reported to the agency.

To protect workers, the Occupational Safety and Health Administration (OSHA) has set an average limit of 1 mg/m³ for zinc chloride fumes and 5 mg/m³ for zinc oxide (dusts and fumes) in workplace air during an 8-hour workday, 40-hour workweek.

Similarly, the National Institute for Occupational Safety and Health (NIOSH) has set the same standards for up to a 10-hour workday over a 40-hour workweek.

SECTION 1 – INCREMENTAL RISK RESULTS FOR RESIDENCES LOCATED ON THE ITALIAN ECONOMY BY STUDY AREA

The purpose of this appendix is to identify the media and constituents responsible for the majority of the incremental risks in the Naples area of Campania by evaluating all of the data, regardless of the Sampling Event, collected during the Public Health Evaluation (PHE). The approach used to evaluate the data presented in this appendix is identical to the approach used for the Phase I & II Screening Risk Evaluation (SRE), except that it utilizes all sampling results (i.e., data from all Sampling Events) to identify key findings and trends that were observed with regard to regional risks. The approach used to evaluate risks for both the Phase I & II SRE and this appendix are presented in detail in Sections 2, 3 and 4 of the main text and are summarized below.

Section 2: This section provides detailed information on the four Sampling Events (Phase I, Pre-Lease, Step-Outs and Phase II) included in this evaluation. This section also outlines the media and constituents sampled during the PHE.

Section 3: This section presents the conceptual site model which defines the potential for exposure, under current and future land uses, to constituents within a study area based on the source(s) of contamination, the release mechanism(s), the exposure pathway(s), and the receptor(s). Risk-based screening levels that were used to evaluate risks for receptors (e.g., workers and residents) are identified in this section.

Section 4: This section presents the risk evaluation by comparing the constituents of potential concern (COPCs) identified in Section 2 with the risk-based screening levels identified in Section 3. Subsections 4.1 through 4.3 present the methods used to calculate and evaluate the risks, as well as the PHE risk management criteria that were used to determine if risks were Acceptable or Unacceptable.

Five hundred and forty-three (543) residences on the economy were sampled as part of the SRE. Of the 543 residences, 130 were sampled as part of the Phase I Sampling Event, 240 were sampled as part of the Pre-Lease Sampling Event, 36 were sampled as part of the Step-Out Sampling Events, and 209 were sampled as part of the Phase II Sampling Event¹. These residences were distributed throughout nine study areas as presented in Table F-1 and presented on Figure F-1. Individual letter reports (i.e., Resident Letters) were provided to each resident, which presented the analytical results for all samples that were collected at their residence, the potential risks, PHE risk-management category, actions that the United States Navy (USN) implemented based on the results, and actions that they (the resident) could take based on the results. Table F-2 summarizes the potential incremental risks for all 543 residences sampled as part of the PHE and the risk-management category for each residence.

¹ Six hundred fifteen samples were collected from 543 residences during the PHE. Seventy-two of the residences were sampled (and re-sampled) during multiple sampling events (for a total of 615 samples). In most cases, the 72 residences were only re-sampled for media that were not sampled during previous sampling events.

The incremental risks associated with the 543 residences sampled on the economy were summarized for each study area and the results are presented in this appendix. Medium-specific and COPC-specific summaries are presented for media/COPCs that contributed significantly to the risk in each study area. For the purposes of this appendix, media/COPCs that contributed significantly to the risks were defined as COPCs with concentrations that exceeded regional screening levels (RSLs), United States maximum contaminant levels (USMCLs), or other screening criteria (e.g., Integrated Exposure Uptake Biokinetic [IEUBK] model and National Ambient Air Quality Standards [NAAQs]) used in this evaluation.

To minimize the number of tables and figures, the same table or figure may be referenced in multiple sections of this appendix. Pathway-specific risk results are presented in Figures F-2 through F-7:

- Figure F-2 presents the total ingestion and inhalation cumulative noncancer risk results (CNCEFs) and cumulative cancer risk results (CCEFs). That is, the total ingestion and inhalation CCEFs and CNCEFs were calculated across all media, assuming exposure via tap water (ingestion+inhalation) for public-water and private-well sources, soil, and soil gas.
- Figure F-3 presents the tap water (ingestion+inhalation) cumulative risk results.
- Figure F-4 presents the soil cumulative risk results.
- Figure F-5 presents soil gas cumulative risk results.
- Figure F-6 presents total inhalation cumulative risk results. That is, the total inhalation CCEFs and CNCEFs were calculated across all media, assuming exposure via tap water (inhalation only) for public-water and private-well sources, soil, and soil gas.
- Figure F-7 presents the tap water inhalation cumulative risk results.

COPC-specific figures for the residences are presented in Figures F-8 through F-44. Rather than creating one figure for each COPC for each study area (i.e., nine separate figures for one COPC), only one figure was created for each COPC (for each pathway) and all nine study areas are presented on that one figure. Figures are organized alphabetically by COPC, and then by pathway (tap water [ingestion+inhalation], tap water [inhalation only], soil, and soil gas), where at least one exceedance has been identified². This approach minimized the number of figures, but also facilitated evaluating spatial trends that were present when evaluating the data holistically.

COPCs detected in soil gas were classified into three groups so that the risks could be calculated appropriately. For detailed information regarding the approach for classifying COPCs detected in soil gas, see *Technical Memorandum: Identification of Chemicals in Soil Gas That May be Associated with Vapor Intrusion*, which is Appendix D of Phase I & II SRE main text (and appendix C.2 of the May 2010 QAPP) (PIONEER Technologies Corporation [PIONEER], 2009). As discussed in Section 4.1 and Appendix D, only COPCs determined to be vapor intrusion (VI) COPCs were included in the risk calculation for soil gas. Risks for the non-VI COPCs were calculated using ambient air results.

Ambient air samples were collected to evaluate the potential exposure via the inhalation of ambient (i.e., outdoor) air impacted by typical urban point sources, non-point sources, and random burning of trash in

areas of the Campania Region. Because ambient air is more regional in nature than concentrations of constituents in tap water, soil and soil gas, an ambient air sampling station was set up in each of the nine study areas to provide regional/spatial coverage across the Naples area. The 95% upper confidence level (UCL) on the mean ambient air concentration was used to determine the reasonable maximum exposure (RME) concentration for each study area (see Table F-12) according to the methodology described in Section 4.1 of the Phase I & II SRE. These RME concentrations were compared to USEPA residential-based RSLs for ambient air, and CEFs and NCEF were calculated for all detected COPCs for each study area (See Table F-13).

For ambient air, no suitable background concentrations for the Campania Region could be located in the scientific literature. Therefore, to provide context, the 95th UCL on the mean concentration from data obtained for six U.S. cities (i.e., San Diego, California; Los Angeles, California; Seattle, Washington; Houston, Texas; Midlothian, Texas; and Washington D.C.) from the USEPA's 2007 Air Toxics Database (USEPA, 2007) was used to represent typical urban background concentrations (henceforth referred to as typical urban air). Exposure point concentrations (EPCs) were calculated for the USEPA's 2007 Air Toxics data using the same methodology as was used for the Naples PHE ambient air data (see Section 4.1 of the Phase I & II SRE). The EPCs for the USEPA's 2007 Air Toxics Database are presented in Table F-12 next to the individual study area EPC (RME concentrations) for comparison. In addition, the USEPA's 2007 Air Toxics Database EPCs were also compared to USEPA residential-based RSLs for ambient air.

A brief summary of the ambient air risks by study area (focusing on the nine constituents of concern [COCs] identified in Section 1.10) is provided for each study area. Where available, CCEF and CNCEF for the COCs were compared to CCEF and/or CNCEF calculated from the USEPA's 2007 Air Toxics Database (i.e., typical urban air). However, it is important to note that some of the constituents detected in the nine study areas did not have corresponding values in the USEPA's 2007 Air Toxics Database. When those constituents (e.g., 1,2-dibromo-3-chloropropane, which was responsible for, on average, 80% of the cancer risks in each study area) were not included in the calculations of the cumulative EFs, the CCEF for the nine study areas were less than the typical urban air in the U.S. in all but one study area (i.e., Study Area 8) (see Table F-14). The CNCEF did not change appreciably (i.e., the difference was less than one percent) when the cumulative EFs were recalculated using only constituents that had corresponding values in the USEPA's 2007 Air Toxics Database, primarily because acrolein (the constituent that contributed the majority of the CNCEF in the Campania Region) had values in both data sets (see Table F-14). A description of the ambient air risk from a regional perspective is presented in Section 1.10.

1.1 Study Area 1

Samples were collected from 125 residences located throughout Study Area 1 (see Figure F-1). One hundred and twenty-two of these residences obtained their tap water from a public water system and three

² This includes figures for COPCs and pathways where there was an exceedance of the RSL that did not result in an Unacceptable risk.

residences obtained their tap water from private wells. The incremental risks for these residences are summarized in Table F-3 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure – 26 of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.0005 to 3.2, the total CCEFs ranged from 0.0004 to 84.2, and there were four residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at 20 residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Bis(2-ethylhexyl)phthalate (Figure F-16)
 - ◆ Copper (Figure F-22)
 - ◆ Fluoride (Figure F-25)
 - ◆ Lead (Figure F-28)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Bis(2-ethylhexyl)phthalate (Figure F-16)
 - ◆ Total coliforms (Figure F-38)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Uranium (Figure F-43)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ No COPCs were detected in tap water samples at concentrations exceeding USMCLs.
 - Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
 - Soil gas was responsible for the Unacceptable risks at five residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,2-Dichloropropane (Figure F-10)
 - ◆ 1,4-Dichlorobenzene (Figure F-12)
 - ◆ Benzene (Figure F-15)
 - ◆ Bromoform (Figure F-17)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)

- ◆ Hexachlorobutadiene (Figure F-26)
- ◆ Methyl tert-Butyl Ether (Figure F-29)
- ◆ Naphthalene (Figure F-30)
- ◆ Tetrachloroethene (Figure F-32)
- ◆ Trichloroethene (Figure F-42)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – Eight of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.00002 to 0.21, the total CCEFs ranged from 0.06 to 82.0, and there were three residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at three residences in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ No COPCs were detected in tap water samples at concentrations exceeding RSLs.
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ No COPCs were detected in tap water samples at concentrations exceeding RSLs.
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ No COPCs were detected in tap water samples at concentrations exceeding USMCLs.
 - Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxin/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
 - Soil gas was responsible for the Unacceptable risks at five residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,2-Dichloropropane (Figure F-10)
 - ◆ 1,4-Dichlorobenzene (Figure F-12)
 - ◆ Benzene (Figure F-15)
 - ◆ Bromoform (Figure F-17)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Methyl tert-Butyl Ether (Figure F-29)
 - ◆ Naphthalene (Figure F-30)
 - ◆ Tetrachloroethene (Figure F-32)
 - ◆ Trichloroethene (Figure F-42)

1.1.1 Ambient Air

The CCEF and CNCEF in Study Area 1 were 553 and 128, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 1 were 111 and 127, respectively.

The following COCs were identified in ambient air in Study Area 1:

- 1,2-Dibromo-3-chloropropane contributed to 79% of the CCEF with a constituent-specific CEF of 439. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 96% of the CNCEF and the constituent-specific NCEF (123) was greater than the NCEF for typical urban air (29).
- 1,2-Dichloropropane contributed to 6.3% of the CCEF and the constituent-specific CEF (35) was greater than the CEF for typical urban air (0.3).
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.2 Study Area 2

Samples were collected from 30 residences³ located throughout Study Area 2 (see Figure F-1). All of these residences sampled obtained their tap water from a public water system. The incremental risks for these residences are summarized in Table F-4 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure – 18 of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.22 to 6.3, the total CCEFs ranged from 0.009 to 103.1 and there were two residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at 17 residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Lead (Figure F-28)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-37)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-37)

³ This included Flag Officer Quarter #07 but did not include Flag Officer Quarters #01 through #06.

- ◆ Total coliforms (Figure F-38)
- Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
- Soil gas was not responsible for Unacceptable risks at any residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,1,2-Tetrachloroethane (Figure F-8)
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Tetrachloroethene (Figure F-32)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – Two of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.0004 to 0.07, the total CCEFs ranged from 0.21 to 13.3, and there was one residence with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at one residence in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ No COPCs were detected in tap water samples at concentrations exceeding RSLs.
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
 - Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - Soil gas was not responsible for Unacceptable risks at any residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,1,2-Tetrachloroethane (Figure F-8)
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Tetrachloroethene (Figure F-32)

1.2.1 Ambient Air

The CCEF and NCEF in Study Area 2 were 791 and 103, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 2 were 136 and 102, respectively.

The following COCs were identified in ambient air in Study Area 2:

- 1,2-Dibromo-3-chloropropane contributed to 82% of the CCEF with a constituent-specific CEF of 650. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 94% of the CNCEF and the constituent-specific NCEF (96) was greater than the NCEF for typical urban air (29).
- 1,2-Dichloropropane contributed to 2.3% of the CCEF and the constituent-specific CEF (18) was greater than the CEF for typical urban air (0.3).
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.3 Study Area 3

Samples were collected from 21 residences⁴ located throughout Study Area 3 (see Figure F-1). All of the residences sampled obtained their tap water from a public water system. The incremental risks for these residences are summarized in Table F-5 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure – Three of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.09 to 2.1, the total CCEFs ranged from 0.01 to 9.6, and there were zero residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at three residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Lead (Figure F-28)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ No COPCs were detected in tap water at concentrations exceeding USMCLs.
 - Soil was not responsible for the Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - Soil gas was not responsible for Unacceptable risks at any residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,2-Dichloropropane (Figure F-10)
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)

⁴ Residences #1856 and 1884 are located east of Study Area 3 but were included in the discussion because Study Area 3 is the closest study area to these locations.

- ♦ Ethylbenzene (Figure F-23)
- ♦ Tetrachloroethene (Figure F-32)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – None of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.0000004 to 0.32, the total CCEFs ranged from 0.0001 to 9.1, and there were no residences with exceedances of USMCLs.
 - Tap water was not responsible for Unacceptable risks at any residences in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ♦ No COPCs were detected in tap water at concentrations exceeding RSLs.
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ♦ No COPCs were detected in tap water at concentrations exceeding USMCLs.
 - Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ♦ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - Soil gas was not responsible for Unacceptable risks at any residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ♦ 1,2-Dichloropropane (Figure F-10)
 - ♦ Benzene (Figure F-15)
 - ♦ Chloroform (Figure F-21)
 - ♦ Ethylbenzene (Figure F-23)
 - ♦ Tetrachloroethene (Figure F-32)

1.3.1 Ambient Air

The CCEF and CNCEF in Study Area 3 were 846 and 172, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 3 were 112 and 171, respectively.

The following COCs were identified in ambient air in Study Area 3:

- 1,2-Dibromo-3-chloropropane contributed to 86% of the CCEF with a constituent-specific CEF of 727. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 96% of the CNCEF and the constituent-specific NCEF (166) was greater than the NCEF for typical urban air (29).
- 1,2-Dichloropropane contributed to 3.3% of the CCEF and the constituent-specific CEF (28) was greater than the CEF for typical urban air (0.3).
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.4 Study Area 4

Samples were collected from 19 residences located throughout Study Area 4 (see Figure F-1). All of the residences sampled obtained their tap water from a public water system. The incremental risks for these residences are summarized in Table F-6 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure – Four of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.17 to 2.4, the total CCEFs ranged from 0.16 to 118.0, and there was one residence with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at three residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
 - Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - Soil gas was responsible for the Unacceptable risks at one residence in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexane (Figure F-27)
 - ◆ Tetrachloroethene (Figure F-32)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – Two of the residences sampled had risks that are considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.00002 to 2.2, the total CCEFs ranged from 0.06 to 116.5, and there was one residence with an exceedance of the USMCL.
 - Tap water was responsible for the Unacceptable risks at one residence in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ No COPCs were detected in tap water at concentrations exceeding RSLs.

- Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
- Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
- Soil gas was responsible for the Unacceptable risks at one residence in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexane (Figure F-27)
 - ◆ Tetrachloroethene (Figure F-32)

1.4.1 Ambient Air⁵

The CCEF and CNCEF in Study Area 4 were 495 and 75, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 4 were 94 and 75, respectively.

The following COCs were identified in ambient air in Study Area 4:

- 1,2-Dibromo-3-chloropropane contributed to 80% of the CCEF with a constituent-specific CEF of 397. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 95% of the CNCEF and the constituent-specific NCEF (72) was greater than the NCEF for typical urban air (29).
- 1,2-Dichloropropane contributed to 2.3% of the CCEF and the constituent-specific CEF (11) was greater than the CEF for typical urban air (0.3).
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.5 Study Area 5

Samples were collected from 114 residences located throughout Study Area 5 (see Figure F-1). One hundred and one of these residences obtained their tap water from a public water system and 13 residences obtained their tap water from private wells. The incremental risks for these residences are summarized in Table F-7 and are discussed below:

⁵ The sampling station for Study Area 4 – Carney Park was actually located in Study Area 1 but was used to evaluate ambient air in Study Area 4.

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure Scenario – 31 of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.10 to 4.5, the total CCEF_s ranged from 0.0004 to 257.1, and there were 16 residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at 24 residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Copper (Figure F-22)
 - ◆ Fluoride (Figure F-25)
 - ◆ Lead (Figure F-28)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Fecal coliform (Figure F-24)
 - ◆ Total coliforms (Figure F-38)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Fluoride (Figure F-25)
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-37)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Fecal coliform (Figure F-24)
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total coliforms (Figure F-38)
 - Soil was responsible for the Unacceptable risks at two residences in this study area⁶ (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
 - Soil gas was responsible for the Unacceptable risks at 9 residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:

⁶ Remedial actions were implemented at both residences and the risks associated with exposure to soil were then considered Acceptable.

- ◆ 1,1,1,2-Tetrachloroethane (Figure F-8)
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Tetrachloroethene (Figure F-32)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – 21 of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.0001 to 0.15, the total CCEFs ranged from 0.003 to 89.6, and there were 13 residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at 14 residences in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ No COPCs were detected in tap water at concentrations exceeding RSLs.
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Fecal coliform (Figure F-24)
 - ◆ Total coliforms (Figure F-38)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Tetrachloroethene (Figure F-34)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Fecal coliform (Figure F-24)
 - ◆ Total coliforms (Figure F-38)
 - Soil was responsible for the Unacceptable risks at two residences in this study area⁷ (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
 - Soil gas was responsible for the Unacceptable risks at 9 residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,1,2-Tetrachloroethane (Figure F-8)
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Tetrachloroethene (Figure F-32)

⁷ See footnote number 6.

1.5.1 Ambient Air

The CCEF and CNCEF in Study Area 5 were 701 and 130, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 5 were 123 and 129, respectively.

The following COCs were identified in ambient air in Study Area 5:

- 1,2-Dibromo-3-chloropropane contributed to 81% of the CCEF with a constituent-specific CEF of 567. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 95% of the CNCEF and the constituent-specific NCEF (124) was greater than the NCEF for typical urban air (29).
- 1,2-Dichloropropane contributed to 4.1% of the CCEF and the constituent-specific CEF (28) was greater than the CEF for typical urban air (0.3).
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.6 Study Area 6

Samples were collected from 59 residences⁸ located throughout Study Area 6 (see Figure F-1). Fifty-eight of these residences obtained their tap water from a public water system and one residence obtained its tap water from a private well. The incremental risks for these residences are summarized in Table F-8 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure Scenario – 20 of the residences⁹ sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.0006 to 33.6, the total CCEFs ranged from 0.0004 to 29,193.6, and there were six residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at 14 residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Fluoride (Figure F-25)
 - ◆ Lead (Figure F-28)
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)

⁸ Residences #1194 and 2105 are located east of Study Area 6 but were included in the discussion because Study Area 6 is the closest study area to these locations.

⁹ The risk result at residence #1877 was inconclusive due to a data gap associated with the lack for speciation for radionuclides and was not included in this count.

- ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
- ◆ Uranium (Figure F-43)
- Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Nitrate (measured as NO₃⁻) (Figure F-31)
 - ◆ Thallium (Figure F-35)
 - ◆ Total coliforms (Figure F-38)
- Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Carbon tetrachloride (Figure F-19)
 - ◆ Nitrate (measured as NO₃⁻) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Uranium (Figure F-43)
- Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Nitrate (measured as NO₃⁻) (Figure F-31)
 - ◆ Total coliforms (Figure F-38)
- Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
- Soil gas was responsible for the Unacceptable risks at 5 residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,2,2-Tetrachloroethane (Figure F-9)
 - ◆ 1,2-Butadiene (Figure F-11)
 - ◆ Acrylonitrile (Figure F-14)
 - ◆ Benzene (Figure F-15)
 - ◆ Carbon Tetrachloride (Figure F-18)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Tetrachloroethene (Figure F-32)
 - ◆ Vinyl Chloride (Figure F-44)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – Six of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.00002 to 30.5, the total CCEFs ranged from 0.09 to 29,177.6, and there were two residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at two residences in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:

- ◆ No COPCs were detected in tap water at concentrations exceeding RSLs.
- Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
- Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Carbon Tetrachloride (Figure F-20)
- Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
- Soil was not responsible Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
- Soil gas was responsible for the Unacceptable risks at 5 residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,2,2-Tetrachloroethane (Figure F-9)
 - ◆ 1,2-Butadiene (Figure F-11)
 - ◆ Acrylonitrile (Figure F-14)
 - ◆ Benzene (Figure F-15)
 - ◆ Carbon Tetrachloride (Figure F-18)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Tetrachloroethene (Figure F-32)
 - ◆ Vinyl Chloride (Figure F-44)

1.6.1 Ambient Air

The CCEF and CNCEF in Study Area 6 were 784 and 127, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 6 were 126 and 126, respectively.

The following COCs were identified in ambient air in Study Area 6:

- 1,2-Dibromo-3-chloropropane contributed to 78% of the CCEF with a constituent-specific CEF of 611. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 95% of the CNCEF and the constituent-specific NCEF (121) was greater than the NCEF for typical urban air (29).

- Total Dioxins/Furans (2,3,7,8-TCDD TEQs) contributed 5% to the CCEF with a constituent-specific CEF of 40. Comparable background data were lacking for total dioxins/furans (2,3,7,8-TCDD TEQs) so they could not be compared with typical urban air.
- 1,2-Dichloropropane contributed to 3% of the CCEF and the constituent-specific CEF (24) was greater than the CEF for typical urban air (0.3).
- The remaining COCs contributed to less than two percent of the CCEF or NCEF.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.7 Study Area 7

Samples were collected from 41 residences located throughout Study Area 7 (see Figure F-1). Forty of these residences obtained their tap water from a public water system and one residence obtained its tap water from a private well. The incremental risks for these residences are summarized in Table F-9 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure Scenario – 18 of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.12 to 3.4, the total CCEFs ranged from 0.08 to 62.2, and there were seven residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at 18 residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Lead (Figure F-28)
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Total coliforms (Figure F-38)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Fluoride (Figure F-25)
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Uranium (Figure F-43)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total coliforms (Figure F-38)

- Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
- Soil gas was responsible for the Unacceptable risks at one residence in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,2,2-Tetrachloroethane (Figure F-9)
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Tetrachloroethene (Figure F-32)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – Eight of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.000005 to 0.25, the total CCEFs ranged from 0.0004 to 12.5, and there were six residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at six residences in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Tetrachloroethene (Figure F-34)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Tetrachloroethene (Figure F-34)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total coliforms (Figure F-38)
 - Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-39)
 - Soil gas was responsible for the Unacceptable risks at one residence in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,2,2-Tetrachloroethane (Figure F-9)
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)

- ◆ Hexachlorobutadiene (Figure F-26)
- ◆ Tetrachloroethene (Figure F-32)

1.7.1 Ambient Air

The CCEF and CNCEF in Study Area 7 were 798 and 253, respectively which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 7 were 122 and 252, respectively.

The following COCs were identified in ambient air in Study Area 7:

- 1,2-Dibromo-3-chloropropane contributed to 83% of the CCEF with a constituent-specific CEF of 663. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 98% of the CNCEF and the constituent-specific NCEF (247) was greater than the NCEF for typical urban air (29).
- 1,2-Dichloropropane contributed to 5.4% of the CCEF and the constituent-specific CEF (43) was greater than the CEF for typical urban air (0.3).
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.8 Study Area 8

Samples were collected from 123 residences located throughout Study Area 8 (see Figure F-1). Sixty-three of these residences obtained their tap water from a public water system and 60 residences obtained their tap water from private wells. The incremental risks for these residences are summarized in Table F-10 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure Scenario – 89 of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.002 to 13.7, the total CCEFs ranged from 0.01 to 867.9, and there were 49 residences with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at 70 residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Copper (Figure F-22)
 - ◆ Lead (Figure F-28)
 - ◆ Nitrate (measured as NO₃-) (Figure F-31)
 - ◆ Tetrachloroethene (Figure F-33)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)

- Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ♦ Fecal coliform (Figure F-24)
 - ♦ Nitrate (measured as NO₃-) (Figure F-31)
 - ♦ Total coliforms (Figure F-38)
- Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ♦ Copper (Figure F-22)
 - ♦ Fluoride (Figure F-25)
 - ♦ Lead (Figure F-28)
 - ♦ Nitrate (measured as NO₃-) (Figure F-31)
 - ♦ Tetrachloroethene (Figure F-33)
 - ♦ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ♦ Uranium (Figure F-43)
- Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ♦ Fecal coliform (Figure F-24)
 - ♦ Nitrate (measured as NO₃-) (Figure F-31)
 - ♦ Tetrachloroethene (Figure F-33)
 - ♦ Total coliforms (Figure F-38)
- Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ♦ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
- Soil gas was responsible for the Unacceptable risks at 28 residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ♦ 1,1,1,2-Tetrachloroethane (Figure F-8)
 - ♦ 1,1,2,2-Tetrachloroethane (Figure F-9)
 - ♦ 1,2-Dichloropropane (Figure F-10)
 - ♦ 1,3-Butadiene (Figure F-11)
 - ♦ 1,4-Dichlorobenzene (Figure F-12)
 - ♦ Acrylonitrile (Figure F-14)
 - ♦ Benzene (Figure F-15)
 - ♦ Carbon Tetrachloride (Figure F-18)
 - ♦ Chloroform (Figure F-21)
 - ♦ Ethylbenzene (Figure F-23)
 - ♦ Hexachlorobutadiene (Figure F-26)
 - ♦ Hexane (Figure F-27)
 - ♦ Tetrachloroethene (Figure F-32)
 - ♦ Trichloroethene (Figure F-42)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – 71 of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria

(see Figure F-6). The total CNCEFs ranged from 0.0001 to 2.7, the total CCEFs ranged from 0.01 to 819.3, and there were 45 residences with exceedances of USMCLs.

- Tap water was responsible for the Unacceptable risks at 48 residences in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Tetrachloroethene (Figure F-34)
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Fecal coliform (Figure F-24)
 - ◆ Total coliforms (Figure F-38)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ Tetrachloroethene (Figure F-34)
 - Residences on Well Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Fecal coliform (Figure F-24)
 - ◆ Total coliforms (Figure F-38)
- Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
- Soil gas was responsible for the Unacceptable risks at 28 residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ 1,1,1,2-Tetrachloroethane (Figure F-8)
 - ◆ 1,1,2,2-Tetrachloroethane (Figure F-9)
 - ◆ 1,2-Dichloropropane (Figure F-10)
 - ◆ 1,3-Butadiene (Figure F-11)
 - ◆ 1,4-Dichlorobenzene (Figure F-12)
 - ◆ Acrylonitrile (Figure F-14)
 - ◆ Benzene (Figure F-15)
 - ◆ Carbon Tetrachloride (Figure F-18)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Hexane (Figure F-27)
 - ◆ Tetrachloroethene (Figure F-32)
 - ◆ Trichloroethene (Figure F-42)

1.8.1 Ambient Air

The CCEF and CNCEF in Study Area 8 were 817 and 101, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air

Toxics Database (see Table F-15). When cumulative risks were calculated including only those constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 8 were 204 and 100, respectively.

The following COCs were identified in ambient air in Study Area 8:

- 1,2-Dibromo-3-chloropropane contributed to 72% of the CCEF with a constituent-specific CEF of 586. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 93% of the CNCEF and the constituent-specific NCEF (93) was greater than the NCEF for typical urban air (29).
- Benzene contributed to 8.3% of the CCEF and the constituent-specific CEF (68) was greater than the CEF for typical urban air (5.2)
- 1,2-Dichloropropane contributed to 3.2% of the CCEF and the constituent-specific CEF (26) was greater than the CEF for typical urban air (0.3).
- Total dioxins/furans (2,3,7,8-TCDD TEQs) contributed 2.6% to the CCEF with the constituent-specific CEF of 21. Comparable background data were lacking for total dioxins/furans (2,3,7,8-TCDD TEQs) so they could not be compared with typical urban air.
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.9 Study Area 9

Samples were collected from 11 residences¹⁰ located throughout Study Area 9 (see Figure F-1). All of the residences sampled obtained their tap water from a public water system. The incremental risks for these residences are summarized in Table F-11 and are discussed below:

- Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure Scenario – Two of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-2). The total CNCEFs ranged from 0.11 to 3.9, the total CCEFs ranged from 0.11 to 53.4, and there was one residence with exceedances of USMCLs.
 - Tap water was responsible for the Unacceptable risks at two¹¹ residences in this study area (see Figure F-3).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ 4-Chloroaniline (Figure F-13)
 - ◆ Lead (Figure F-28)
 - ◆ Total dioxins/furans (2,3,7,8-TCDD TEQs) (Figure F-40)
 - ◆ Uranium (Figure F-43)

¹⁰ Residences #0200 and 1906 are located north of Study Area 9 but were included in the discussion because Study Area 9 is the closest study area to these residences.

¹¹ Residence #1906 had an Unacceptable risk, but is not reflected on Figure F-3 because it is located north of Study Area 9 and falls outside of the extent of this figure.

- Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ Total trihalomethanes (Figure F-41)
- Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
- Soil gas was not responsible for Unacceptable risks at any residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Tetrachloroethene (Figure F-32)
- Tap Water (via Inhalation Only), Soil, and Soil Gas Exposure Scenario – None of the residences sampled had risks that were considered Unacceptable based on the PHE risk management criteria (see Figure F-6). The total CNCEFs ranged from 0.002 to 0.11, the total CCEFs ranged from 1.3 to 8.8, and there were no residences with exceedances of USMCLs.
 - Tap water was not responsible for Unacceptable risks at any residences in this study area (see Figure F-7).
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding RSLs:
 - ◆ No COPCs were detected in tap water at concentrations exceeding RSLs.
 - Residences on Public Water – The following COPCs were detected in tap water samples at concentrations exceeding USMCLs:
 - ◆ No COPCs were detected in tap water at concentrations exceeding USMCLs.
 - Soil was not responsible for Unacceptable risks at any residences in this study area (see Figure F-4). The following COPCs were detected in soil at concentrations exceeding RSLs:
 - ◆ Total carcinogenic PAHs (BaP TEQs) (Figure F-36)
 - Soil gas was not responsible for Unacceptable risks at any residences in this study area (see Figure F-5). The following COPCs were detected in soil gas at concentrations exceeding RSLs:
 - ◆ Benzene (Figure F-15)
 - ◆ Chloroform (Figure F-21)
 - ◆ Ethylbenzene (Figure F-23)
 - ◆ Hexachlorobutadiene (Figure F-26)
 - ◆ Tetrachloroethene (Figure F-32)

1.9.1 Ambient Air

The CCEF and CNCEF in Study Area 9 were 709 and 143, respectively, which exceeded the typical urban air cancer (160) and noncancer (33) risks that were calculated based on the USEPA's 2007 Air Toxics Database (see Table F-15). When cumulative risks were calculated including only those

constituents with corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF in Study Area 9 were 104 and 142, respectively.

The following COCs were identified in ambient air in Study Area 9:

- 1,2-Dibromo-3-chloropropane contributed to 80% of the CCEF with a constituent-specific CEF of 569. Comparable background data were lacking for 1,2-dibromo-3-chloropropane so it could not be compared with typical urban air.
- Acrolein contributed to 97% of the CNCEF and the constituent-specific NCEF (139) was greater than the NCEF for typical urban air (29).
- Total dioxins/furans (2,3,7,8-TCDD TEQs) contributed 4.3% to the CCEF with a constituent-specific CEF of 30. Comparable background data were lacking for total dioxins/furans (2,3,7,8-TCDD TEQs) so they could not be compared with typical urban air.
- The remaining COCs each contributed less than two percent to the cumulative EFs.

See Section 1.10 for a regional summary of ambient air across the nine study areas.

1.10 Risks Associated with Ambient Air in Study Areas 1 through 9

Note: Incremental risks could not be calculated for ambient air because background concentrations were not available for Naples, Italy (see Section 4.2 in the main report). Therefore, only total risks could be calculated. The following information is based on total risks.

To determine the cumulative EFs for each study area, CEFs and NCEF for individual COPCs were totaled¹² and a summary of the total ambient air risks associated with each study area are presented in Table F-14. The CCEF and CNCEF for the study areas ranged from 495 to 846 and from 75 to 253, respectively, when all constituents detected in ambient air during the Naples PHE were included in the calculation. Both cancer and noncancer risks exceeded the risks calculated from the USEPA's 2007 Air Toxics Database (USEPA, 2007a) for typical urban air (i.e., CCEF of 160 and CNCEF of 33). However, when cumulative risks were calculated including only those constituents that had corresponding values in the USEPA's 2007 Air Toxics Database, the CCEF and CNCEF for the study areas ranged from 94 to 204 and from 75 to 252, respectively.

Twenty-seven COPCs had EPCs that exceeded RSLs in at least one study area (see Table F-15). To focus the evaluation on the COPCs that contributed the majority of the ambient air risk, the COPCs were evaluated further and COCs were identified based on the following criteria:

1. The EPC was greater than the NAAQs; and/or
2. The CEF and/or NCEF associated with the EPC were greater than 10 or greater than one, respectively in at least one study area; and

¹² While summing the risk for all constituents detected is often used for screening purposes, it likely overestimates potential risk. A more accurate calculation would involve creating a separate total for each mechanism of action (or toxic endpoint as a surrogate).

3. The COPC RME EPC was greater than the EPC from the USEPA's 2007 Air Toxics Database for typical U.S. urban air (USEPA, 2007).

Based on this evaluation, nine of the 27 COPCs were identified as COCs (see Table F-16). Key findings associated with the regional distribution of ambient air incremental risks are discussed in Section 2.1.3.

SECTION 2 – FINDINGS

The purpose of this section is to summarize the media and constituents responsible for the majority of the risks, using the data collected during Phase I and Phase II of the SRE, and also identify trends that have been observed with regards to regional risks based on the Phase I and Phase II data. This discussion is presented in the following sections:

- The regional summary of incremental risks for Phase I and Phase II residences is presented in Section 2.1.
- The regional distribution of incremental risks for Phase I and Phase II is discussed in Section 2.2.

This appendix presents general conclusions about the potential health risks associated with living in the Naples area of Campania based on the results of all residences sampled during the SRE. These conclusions and any future conclusions, statistical evaluations, summaries, and risk management decisions should consider/incorporate the limitations of the methodology used in the risk assessment and the unique conditions/limitations under which the PHE was performed.

For example, the Phase I and the Step-Out Sampling Events were based on a *biased* sampling design and were intended to identify “worst-case” locations and further investigate areas proximate to residences with Unacceptable risks, respectively. In contrast, the Phase II Sampling Event was based on a *random* sampling design and was intended to obtain broad geographical coverage throughout each study area. These sampling designs were established to answer very specific, and different, questions. Therefore, when evaluating these data collectively, as presented in this appendix, it was not appropriate to present specific conclusions, such as the average risk in a study area or compare average risks between study areas.

In addition, the USN could not sample or investigate (e.g., install groundwater monitoring wells, et cetera) potential or suspected areas of contamination resulting from illicit disposal activities as it would in the U.S. Consequently, only residences on the Italian economy where USN Personnel lived (or may live in the future) could be sampled. This limitation influenced the aggregate percentages of Unacceptable residences presented in this appendix.

2.1 Regional Summary of Incremental Risks for All Residences Sampled During the PHE

Five hundred and forty-three (543) residences were sampled for tap water, soil, and soil gas during PHE (although not all media were sampled at every residence). As discussed in the introduction to this appendix, the incremental risks in this SRE were calculated for two different scenarios for all media: (1) assuming tap water exposure via ingestion and inhalation and (2) assuming tap water exposure via inhalation only. Table F-2 presents detailed risk information for every residence that was sampled during the PHE. Tables F-3 through F-11 summarize the information presented on Table F-2 by presenting the number of residences with Unacceptable risks, range of total CNCEFs and total CCEFs, and media and constituents responsible for the majority of the risks for each study area.

Twenty-two percent (118 of 543) of the residences sampled during the PHE had Unacceptable risks based on the Tap Water (Inhalation-Only), Soil, and Soil Gas Scenario (32% [41 of 130] and 22% [46 of 209] of

the residences sampled during Phase I and Phase II, respectively had Unacceptable risks). Thirty-nine percent (211 of 543) of the residences sampled during the PHE had Unacceptable risks based on the Tap Water (Ingestion+Inhalation), Soil, and Soil Gas Scenario (48% [62 of 130] and 42% [88 of 209] of the residences sampled during Phase I and Phase II, respectively had Unacceptable risks). The box below summarizes the number of residences with Unacceptable risks per study area.

¹ All residences sampled during the PHE represent samples collected during all Sampling Events (i.e., Phase I, Pre-Lease, Step-Outs, and Phase II).									

As shown on Figures F-2 and F-6, the residences with Unacceptable risks are located throughout the study areas, with the highest number of Unacceptable risks observed in Study Area 8 (60 of the 89 residences with Unacceptable risks obtained their tap water from a private well and 60 of the 60 residences that obtained their tap water from a private well had Unacceptable risks). This result was expected. Prior to commencing the PHE, Italian maps and anecdotal information regarding historical waste-disposal practices in agricultural areas (such as Study Areas 5, 6, 7, 8, and 9), which were presented in the press and other literature that were reviewed for the PHE, indicated that Study Area 8 would likely be one of the study areas with a large number of Unacceptable risks. In addition, many of the residences in Study Area 8 obtained their tap water from private wells which are typically more susceptible to contamination from localized dumping of industrial/chemical waste than public water supply systems. The results from Phase I and Phase II indicate that residences that obtained their tap water from private wells (regardless of the study area) had higher frequencies of Unacceptable risks than residences that obtained their tap water from a public source. For example, during Phase I 30 of the 36 (83%) residences that obtained their tap water from a private well had Unacceptable risks, whereas on 18 of the 94 (19%) residences that obtained their tap water from a public source had Unacceptable risks (PIONEER, 2009). The results from Phase II were consistent with Phase I, as 13 of the 13 residences (100%) that obtained their tap water from a private well had Unacceptable risks. Study Areas 3 and 9 had the lowest percentage of Unacceptable risks but also had the fewest number of residences sampled so it is not possible to reach any conclusion regarding the significance of these findings. The number and frequency of Unacceptable risks for Study Areas 1 and 2 were unexpected because these areas are densely populated and do not have expansive agricultural areas or open space which could potentially be used for illegal waste disposal activities. In addition, all of the Phase II residences in Study Areas 1 and 2 obtained their tap water from a public source.

Residences with Acceptable risks and Unacceptable risks were distributed throughout the study areas and often were located very close each other. In other words, the residences with Unacceptable risks were generally randomly distributed (with some exceptions) within the study areas (see Figures F-2 and F-6). Exceptions to this general observation are identified below:

- Risks Based on Tap Water (Inhalation-Only), Soil, and Soil Gas (Figure F-6)
 - There was a cluster of Unacceptable residences in Study Area 8 within the New Lease Suspension Zone (NLSZ).
 - Unacceptable residences located outside of Study Area 8 were often found in clusters of two or three.
- Risks Based on Tap Water (Ingestion+Inhalation), Soil, and Soil Gas (Figure F-2)
 - There is a cluster of Unacceptable residences located in:
 - Study Area 1 (western half of the study area),
 - Study Area 2 (near the U.S. Consulate),
 - Study Area 5 (south of Lago Patria Receiver Site),
 - Study Area 6 (southwest of the Gricignano Support Site) and
 - Study Area 8 (within the NLSZ).

As summarized in the box presented below, the ranges of risks were highly variable and heterogeneous between study areas and within the study areas. This high degree of variability prevented calculating an “average risk” or “upper-bound” risk for each study area or across all study areas. For example, the average total CCEF based on the tap water (Inhalation-Only), soil, and soil gas scenario for all the residences in the PHE for Study Area 1 was 2.1. While low, this average total CCEF perspective inaccurately indicates that the risks within this study area were Acceptable, when in fact, eight of the 125 residences had Unacceptable risks (i.e., the total CCEF was greater than 10) and the range of total CCEFs for Study Area 1 was 0.06 to 82.

¹ All residences sampled during the PHE represent samples collected during all Sampling Events (i.e., Phase I, Pre-Lease, Step-Outs, and Phase II).									

2.1.1 *Media Responsible for the Majority of the Incremental Risks Based On All Residences Sampled During the PHE*

The majority of the Unacceptable incremental risks identified during PHE sampling were associated with COPCs detected in tap water from private wells and soil gas collected from beneath or beside the foundation of the residence. Only two residences, evaluated during Phase I, had Unacceptable risks based solely on soil. In fact, soil sampling was discontinued midway through Phase II because results from Phase I and Phase II indicated that soil contamination did not pose a significant human health risk. The results of the year-long ambient air sampling and monitoring program that was conducted as part of the PHE indicated that risks associated with exposure to ambient air in Naples were greater than the risks calculated from the USEPA's 2007 Air Toxics Database (USEPA, 2007a) for typical U.S. urban air. However, when risk results were calculated included only those constituents that had corresponding values in the USEPA's 2007 Air Toxics Database, the CCEFs were less than the CCEF calculated for typical urban air in the U.S in all but one study area (Study Area 8). The CNCEFs did not change appreciably (i.e., the difference was less than one percent), primarily because acrolein (the constituent that contributed the majority of the CNCEF in the nine study areas) had values in both data sets¹³. The risks associated with tap water, soil, soil gas, and ambient air are summarized below.

- **Tap Water (Inhalation-Only) Scenario**
 - Tap Water from a Public Source: Twenty-four (24) of the 459 residences sampled during the PHE that obtained their tap water from a public source had Unacceptable risks due to concentrations of COPCs in tap water (see Figure F-7). All 24 of the residences had Unacceptable risks due to microorganisms in tap water. Unacceptable residences were distributed randomly throughout the study areas.
 - Tap Water from a Private Well: Fifty-one (51) of the 65 residences sampled during the PHE that obtained their tap water from a private well¹⁴ had Unacceptable risks due to concentrations of COPCs in tap water (see Figure F-7). Forty-seven (47) of the 51 residences had Unacceptable risks due to microorganisms in tap water¹⁵. The majority of residences with Unacceptable results (42 out of 51) were located in Study Area 8.
- **Tap Water (Ingestion+Inhalation) Scenario**
 - Tap Water from a Public Source: One-hundred and eleven (111) of the 459 residences sampled during the PHE that obtained their tap water from a public source had Unacceptable risks due to concentrations of COPCs in tap water (see Figure F-3). Twenty-four (24) of the 111 residences had Unacceptable risks due to microorganisms in tap water¹⁶. These

¹³ For ambient air, no suitable background concentrations for the Campania Region could be located in the scientific literature. Therefore, the 95% UCL on the mean concentration from data obtained for six U.S. cities (i.e., San Diego, California; Los Angeles, California; Seattle, Washington; Houston, Texas; Midlothian, Texas; and Washington DC) from the USEPA's 2007 Air Toxics Database (USEPA, 2007) was used to represent typical urban air. Refer to Section 4.1 in the Naples Public Health Evaluation Volume II: Phase I & II SRE for explanation on the development of EPCs.

¹⁴ The residences that obtained their tap water from a private well were located in Study Area 1 (three residences), Study Area 5 (11 residences), Study Area 6 (one residence), Study Area 7 (one residence), and Study Area 8 (60 residences).

¹⁵ Some of the residences with microorganisms detected in tap water were co-located with the Unacceptable chemical risks in tap water; therefore, the total number of residences with Unacceptable microorganism results plus the total number of residences with Unacceptable chemical results does not always equal the total number of Unacceptable residences.

¹⁶ See footnote 15.

- residences were more randomly distributed within the study areas; with the highest number of Unacceptable results (21 out of 111) located in Study Area 8.
- Tap Water from a Private Well: Sixty (60) of the 65 residences sampled during the PHE that obtained their tap water from a private well had Unacceptable risks due to concentrations of COPCs in tap water (see Figure F-3). Forty-seven (47) of the 60 residences had Unacceptable risks due to microorganisms in tap water¹⁷. These residences were primarily located in Study Area 8 (49 out of 60).
 - **Soil**
 - Two (2) of the 184 residences sampled during the PHE had Unacceptable risks based solely on constituents in soil (See Figure F-4). These residences were located in Study Area 5 and sampled during Phase I.
 - **Soil Gas**
 - Forty-nine (49) of the 300 residences sampled during the PHE had Unacceptable risks based solely on constituents in soil gas (see Figure F-5). Clusters of residences with Unacceptable risks associated solely with constituents detected in soil gas were observed primarily in Study Area 8 (28 out of 49). In addition, residences with Unacceptable risks located outside of Study Area 8 were often found in clusters of two or three residences. The passive soil gas samples collected during Phase I were pooled with the active soil gas samples collected during Phase II. Passive soil gas results can be semi-quantitative, but are typically more qualitative in nature. Seven residences where passive soil gas samples were collected during Phase I were re-sampled during Phase II using active soil gas methods and, in all cases, the active soil gas results were Unacceptable – although the risks in most cases were lower than the passive soil gas risks¹⁸.
 - **Ambient Air**
 - *Note: Incremental risks could not be calculated for ambient air because background concentrations were not available for Naples, Italy (see Section 4.2). Therefore, only total risks could be calculated. The following information is based on total risks.* The CCEFs and CNCEFs for the nine study areas in Naples ranged from 495 to 846 and 75 to 253, respectively, and exceeded the CCEFs and CNCEFs calculated using concentrations representative of typical urban air in the U.S. (160 and 33, respectively) (USEPA, 2007a). However, the risks associated with exposure to ambient air in Naples are not directly comparable to the risks associated with exposure to ambient air in the U.S. because some of the constituents detected in the nine study areas did not have corresponding values in the USEPA's 2007 Air Toxics Database. When those constituents (e.g., 1,2-dibromo-3-chloropropane, which was responsible for, on average, 80% of the cancer risks in each study area) were not included in the calculations of the cumulative EFs, the CCEFs for the nine study areas were less than the typical urban air in the U.S. in all but one study area (i.e., Study Area 8) (see Table F-14). The CNCEFs did not change appreciably (i.e., the difference

¹⁷ See footnote 15.

¹⁸ The risk results for the seven locations were calculated prior to applying a Multi-story VAF. With the multi-story VAF applied, two of the seven locations changed from Unacceptable to Acceptable, see Section 4.5.3 in the main text of this report.

was less than one percent) when the cumulative EFs were recalculated using only constituents that had corresponding values in the USEPA’s 2007 Air Toxics Database, primarily because acrolein (the constituent that contributed the majority of the CNCEF in the nine study areas) had values in both data sets (see Table F-14). Because some constituents (including 1,2-dibromo-3-chloropropane) did not have corresponding values in the USEPA’s 2007 Air Toxics Database, it was not possible to determine whether or not the cumulative ambient air risks in the Campania Region exceeded the risks from typical urban air in the U.S.

2.1.2 Constituents Responsible for the Majority of the Incremental Risks Based on All Residences Sampled During the PHE

The following table identifies constituents that exceeded RSLs and/or USMCLs (USMCLs apply to tap water only) in tap water, soil, soil gas, and/or ambient air based on all residences sampled during the PHE:

COPCs Based on All Residences Sampled During the PHE

Tap Water ¹	Soil	Soil Gas ²	Ambient Air
<p>PRIVATE WELLS</p> <p>RSLs Exceedances: Carbon Tetrachloride Copper Fluoride Lead Nitrate (measured as NO₃-) Tetrachloroethene Total Carcinogenic PAHs (BaP TEQs) Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium</p> <p>USMCL Exceedances: Fecal Coliform Nitrate (measured as NO₃-) Tetrachloroethene Total Coliforms</p> <p>PUBLIC WATER</p> <p>RSLs Exceedances: 4-Chloroaniline Bis(2-ethylhexyl)phthalate Copper Fluoride Lead Nitrate (measured as NO₃-) Tetrachloroethene Total Carcinogenic PAHs (BaP TEQs) Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium</p> <p>USMCL Exceedances: Bis(2-ethylhexyl)phthalate Fecal Coliform Nitrate (measured as NO₃-) Thallium Total Carcinogenic PAHs (BaP TEQs) Total Coliforms</p>	<p>RSLs Exceedances: Total Carcinogenic PAHs (BaP TEQs) Total Dioxin/Furans (2,3,7,8-TCDD TEQs)</p>	<p>RSLs Exceedances: 1,1,1,2-Tetrachloroethane 1,1,2,2-Tetrachloroethane 1,2-Dichloropropane 1,3-Butadiene 1,4-Dichlorobenzene Acrylonitrile Benzene Bromoform Carbon Tetrachloride Chloroform Ethylbenzene Hexachlorobutadiene Hexane Methyl tert-Butyl Ether Naphthalene Tetrachloroethene Trichloroethene Vinyl Chloride</p>	<p>RSLs Exceedances: 1,1,1,2-Tetrachloroethane 1,1,2,2-Tetrachloroethane 1,2-Dibromo-3-Chloropropane 1,2-Dibromoethane 1,2-Dichloroethane 1,2-Dichloropropane 1,3-Butadiene 1,4-Dichlorobenzene Acetaldehyde Acrolein Acrylonitrile Arsenic Benzene Bromodichloromethane Carbon Tetrachloride Chloroform Cobalt Dibromochloromethane Dieldrin Ethylbenzene Formaldehyde Hexachlorobutadiene Hexane Naphthalene Tetrachloroethene Total Carcinogenic PAHs (BaP TEQs) Total Dioxin/Furans (2,3,7,8-TCDD TEQs)</p>

COPCs Based on All Residences Sampled During the PHE

Tap Water ¹	Soil	Soil Gas ²	Ambient Air
Total Trihalomethanes			
¹ Tap water RSLs include both tap water (ingestion + inhalation) and tap water (inhalation only) ² Soil gas constituents include those that were identified as VI COPCs, as per <i>Technical Memorandum: Identification of Chemicals in Soil Gas that may be Associated with Vapor Intrusion</i> , which is presented in Appendix D of the main report (PIONEER, 2009).			

Not all of the COPCs presented in the previous table contributed significantly to the regional risks calculated as part of the SRE. Some of the COPCs infrequently and/or only slightly exceeded their RSLs and/or USMCLs, which indicates that the risk was constrained to a few locations and is not indicative of a larger study area-wide risk or region-wide risk. This should not be construed to imply that some risks are less important or more important than others. All exceedances of RSLs/USMCLs should be treated with concern and addressed accordingly. Appendix H presents U.S. Agency for Toxic Substances and Disease Registry (ATSDR) Chemical Fact Sheets (ToxFAQs™), where available, for each COPC exceedance. Each fact sheet serves as a quick and easy-to-understand guide that discusses exposure to hazardous substances found around hazardous waste sites and the effects of exposure on human health.

In a large regional study such as this PHE, a primary focus is on area-wide or region-wide risks because they are more likely to represent an effect on most of the population (e.g., USN Personnel who may work, play and/or live at different facilities in the study areas at different times). Therefore, the constituents presented in the previous table were evaluated to identify (1) constituents that are potentially an area-wide or region-wide concern and (2) constituents that individually pose an Unacceptable risk in a single or multiple media (i.e., even if the risks for other constituents are not considered). Table F-17 (tap water from a public source – ingestion+inhalation), Table F-18 (tap water from a private well – ingestion+inhalation), Table F-19 (tap water from a public source – inhalation only), Table F-20 (tap water from a private well – inhalation only), Table F-21 (soil), and Table F-22 (soil gas) present the frequency of constituent concentrations that exceeded their RSL and/or USMCL and also the frequency of constituent concentrations that were Unacceptable in relation to their RSL and/or USMCL. Table F-15 (ambient air) presents the 27 COPCs that had RME EPCs that exceeded RSLs in at least one study area. Solely for the purposes of focusing the following discussion, COCs in tap water, soil, and soil gas, and ambient air¹⁹ were identified from Table F-15 and Tables F-17 through F-22 as follows:

1. If greater than 10% of the total number of residences sampled had concentrations greater than the RSL.
2. If greater than 2.5% of the total number of residences sampled had concentrations that were greater than 10 times their RSL and/or greater than their USMCL (tap water only) and/or greater than their NAAQS (air only).

Based on the criteria presented above, the following table presents the COCs that are responsible for the majority of area-wide and region-wide risks based on all residences sampled during the PHE:

COCs Based on All Residences Sampled During the PHE

Tap Water ¹	Soil	Soil Gas ²	Ambient Air
<p><u>PRIVATE WELLS</u></p> <p>RSLs Exceedances: Copper Fluoride Nitrate (measured as NO₃-) Tetrachloroethene Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium</p> <p>USMCL Exceedances: Fecal Coliform Nitrate (measured as NO₃-) Tetrachloroethene Total Coliforms</p> <p><u>PUBLIC WATER</u></p> <p>RSLs Exceedances: Lead Tetrachloroethene Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium</p> <p>USMCL Exceedances: Total Coliforms</p>	<p>RSLs Exceedances: Total Carcinogenic PAHs (BaP TEQs)</p>	<p>RSLs Exceedances: Benzene Chloroform Ethylbenzene Tetrachloroethene</p>	<p>RSLs Exceedances: 1,2-Dibromo-3-Chloropropane 1,2-Dichloropropane Acetaldehyde Acrolein Arsenic Benzene Hexane Tetrachloroethene Total Dioxin/Furans (2,3,7,8-TCDD TEQs)</p>

2.2 Regional Distribution of Incremental Risks Based on All Residences Sampled During the PHE

The evaluation of the regional distribution of incremental risks in the Campania Region was complicated by the spatial/geographic distribution of sampling locations, various sources of tap water (e.g., public or private wells), and biased sampling that was limited to locations where USN Personnel work and live and where the tenant and landlord agreed to allow sampling. Based on all residences sampled during the PHE, COCs in the tap water obtained from private wells (see Figure F-7) and soil gas (see Figure F-5) were responsible for the majority of the Unacceptable risks. These results are consistent with the Phase II results, but contrast with the Phase I results which indicated that the tap water obtained from private wells was responsible for the majority of the risks (i.e., soil gas was only responsible for Unacceptable risks at eight of 110 (7%) residences where soil gas was sampled during Phase I versus 32 of 175 (18%) residences where soil gas was sampled during Phase II). However, this difference might be explained by

¹⁹ For ambient air, COCs were identified from COPCs with an RME EPC that was greater than the EPC based on USEPA's 2007 Air Toxics Database AND where the CEF was greater than 10 and/or NCEF was greater than one and/or the EPC was greater than the NAAQS.

the fact that active soil gas samples were collected during Phase II (i.e., TO-15/SUMMA Canisters) rather than the passive soil gas samples (i.e., Gore-Sorber®) that were collected during Phase I. General observations regarding the regional distribution of risks for each medium sampled are presented below:

- **Tap Water (Inhalation-Only Scenario)** – The majority of residences with Unacceptable concentrations in tap water (based on inhalation only) were located in Study Area 8 where the tap water was obtained from private wells. This observation is consistent with results based solely on Phase I and also with results based solely on Phase II. In the remaining study areas, the frequency of Unacceptable residences was very low and the residences with Unacceptable tap water concentrations were typically (but not in all cases) geographically grouped (i.e., multiple Unacceptable locations were near each other). Therefore, if a residence obtained tap water from a public source and was not located in Study Area 8 or an NLSZ, then the regional data indicated that it was likely that tap water was Acceptable based on the PHE risk management criteria. Fecal coliform, total coliforms, and tetrachloroethene were responsible for the majority of the Unacceptable risks associated with exposure to tap water (via inhalation only).
 - **Tap Water from a Public Source:** Based on the PHE risk management criteria, the regional data indicated that the tap water was likely to be Acceptable if it was obtained from a public source (i.e., 435 of the 459 residences sampled [95%] had Acceptable tap water). This observation is consistent with results based solely on Phase I (92% of tap water results obtained from a public source were Acceptable) and also with results based solely on Phase II (96% of tap water results obtained from a public source were Acceptable). The COCs responsible for the majority of the risks are summarized below:
 - Total coliforms – Five percent of residences sampled had Unacceptable concentrations in their tap water. The Unacceptable total coliforms results were found in all study areas except Study Areas 3 and 9. However, the majority of the Unacceptable results (i.e., 18 of the 24 residences sampled [75%]) were found in Study areas 5, 7, and 8. One possible explanation for these results is the lack of routine disinfection of household tap water holding/storage tanks that are used to maintain the water supply/pressure tanks in residences despite fluctuations in the public water supply distribution system. If these holding/storage tanks are open at the top, animals and other material can enter the tank and may result in an unsanitary condition.
 - **Tap Water from Private Wells:** Based on the PHE risk management criteria, the regional data indicated that the tap water was likely to be Unacceptable if it was obtained from a private well (i.e., 51 of the 65 residences sampled [78%] had Unacceptable tap water). The frequencies of residences with Unacceptable risks based solely on Phase I results and solely on the data for Phase II results were similar at 78% and 80%, respectively. The COCs responsible for the majority of the risks are summarized below:
 - Fecal coliform (28% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable fecal coliform results were found in Study Area 5 (four of the 11 residences sampled) and Study Area 8 (12 of the 41 residences sampled). This is not surprising because at the time samples were collected, the majority of residences that obtained their tap water from private wells were located in these study areas. These

results may be explained by the lack of routine disinfection of household tap water holding/storage tanks, as discussed above, as well as agricultural activities in the area.

- Tetrachloroethene (37% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable tetrachloroethene results were detected in Study Areas 5 and 8.
 - Total coliforms (82% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable total coliforms results were found in Study Areas 5, 6, 7, and 8. However, the majority of the Unacceptable results (i.e., 45 of the 57 residences sampled [79%]) were found in Study Areas 5 and 8. One possible explanation for these results is the lack of routine disinfection of household tap water holding/storage tanks that are used to maintain the water supply/pressure in residences. If these holding/storage tanks are open at the top, animals and other material can enter the tank and may result in an unsanitary condition.
- **Tap Water (Ingestion+Inhalation) Scenario** – The majority of residences with Unacceptable concentrations in tap water, based on ingestion and inhalation exposure pathway, were located in Study Area 8 where the tap water was obtained from private wells. This observation is consistent with Phase I results and also with Phase II results. However, there was a greater frequency of Unacceptable results observed in Study Area 8 during Phase I, which may be associated with the fact that a greater percentage of residences sampled during Phase I obtained their tap water from private wells than those sampled during Phase II. As presented in Figure F-3, with the exception of Study Area 8, residences with Unacceptable risks were randomly distributed throughout the study areas, and the majority of these residences obtained their tap water from a public source. Study Areas 3, 4, and 9 had the fewest number of residences with Unacceptable tap water. However, Study Area 1 (20 of the 125 residences [16%] sampled), and Study Area 2 (17 of the 30 residences [57%] sampled) had a higher-than-expected frequency of Unacceptable concentrations in tap water. These areas are densely populated and do not have expansive agricultural areas or open space, which could potentially be used for illegal waste disposal activities. In addition, all of the residences sampled during Phase II in Study Areas 1 and 2 obtained their tap water from a public source.

Results of aqueduct sampling performed during the Environmental Testing Support Assessment (ETSA) (Tetra Tech, 2010) indicated that water quality from the aqueduct, which is the source of the municipal water supply for the Campania Region, should be Acceptable when compared to USEPA USMCLs following treatment and filtration. Therefore, the constituent contamination that was frequently detected in tap water samples from residences that obtained their tap water from a public source likely entered the public water supply distribution system after the source water had been disinfected. One possible explanation for the presence of contamination in the public water distribution system is back flow of contamination from wells into the public water distribution system from residences that have blended or dual water supplies (i.e., they obtain their water from a municipal supplier and also from a private well). If these residences did not have a backflow preventer or other device that isolated the public water supply line, then when private well water was used to supply water to the residences, contaminants in the well water

would have entered the public water distribution system due to the pressure differences in the lines.

- **Tap Water from a Public Source:** The regional data indicated that it was likely that the tap water was Acceptable based on the PHE risk management criteria if it was obtained from a public source (i.e., 348 of the 459 residences sampled [76%] had Acceptable tap water). This observation is consistent with results based solely on Phase I (75% of tap water results obtained from a public source were Acceptable) and also with results based solely on Phase II (74% of tap water results obtained from a public source were Acceptable). The COCs responsible for the majority of the risks are summarized below:
 - Lead (5% of residences sampled). The Unacceptable lead results were distributed throughout all study areas, except for Study Area 4.
 - Total coliforms (5% of residences sampled). The Unacceptable total coliforms results were found in Study Areas 1, 2, 4, 5, 6, 7, and 8. However, the majority of the Unacceptable results (i.e., 18 of the 24 residences sampled [75%]) were found in Study Areas 5, 7, and 8). One possible explanation for these results is the lack of routine disinfection of household tap water holding/storage tanks that are used to maintain the water supply/pressure in residences despite fluctuations in public water supply distribution system. If these holding/storage tanks are open at the top, animals and other material can enter the tank and may result in an unsanitary condition.
 - Total dioxins/furans [2,3,7,8-TCDD TEQs] (i.e., 62 of the 459 residences sampled [14%]), and uranium (i.e., 141 of the 458 residences sampled [31%]) were detected throughout all nine study areas in tap water and at concentrations exceeding the RSL but below the PHE's risk management criteria for Unacceptable risk. However, the concentrations did not exceed the USMCL and the uranium exceedances are most likely associated with natural background concentrations rather than illicit disposal of radioactive waste.
 - Tetrachloroethene in tap water exceeded its RSLs at 77 of the 459 residences sampled [17%]. RSLs were exceeded in all study areas except for Study Area 5 and Study Area 9.
- **Tap Water from Private Wells:** The regional data indicated that it was likely that tap water was Unacceptable based on the PHE risk management criteria if it was obtained from a private well (i.e., 60 of the 65 residences sampled [92%] had Unacceptable tap water). The frequencies of residences with Unacceptable risks based solely on Phase I results and solely on the data for Phase II results were similar at 86% and 100%, respectively. The COCs responsible for the majority of the risks are summarized below:
 - Copper (11% of residences sampled had Unacceptable concentrations in their tap water). All of the Unacceptable results were detected in Study Area 8.
 - Fecal coliform (28% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable fecal coliform results were found in Study Area 5 (four of the 11 residences sampled) and Study Area 8 (12 of the 41 residences sampled). This is not surprising because at the time samples were collected, the majority of residences that obtained their tap water from private wells were located in these study areas. These

results may be explained by the lack of routine disinfection of household tap water holding/storage tanks, as discussed above, as well as agricultural activities in the area.

- Fluoride (12% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable fluoride results were detected in Study Areas 5, 7, and 8.
 - Nitrate (84% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable nitrate results were detected in Study Areas 5, 6, 7, and 8, which might be explained by the use of nitrogen-based fertilizers in these extensive agricultural areas.
 - Tetrachloroethene (58% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable tetrachloroethene results were detected in Study Areas 5, 7, and 8. Tetrachloroethene also exceeded its RSL in 51 of 65 residences sampled (78%).
 - Uranium (5% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable uranium results were detected in Study Areas 5 and 8. Uranium also was detected in tap water at concentrations exceeding the RSL but below the PHE's risk management criteria for Unacceptable risk in 50 of 57 residences sampled (88%). However, the concentrations did not exceed the USMCL and the uranium exceedances are most likely associated with natural background concentrations rather than illicit disposal of radioactive waste.
 - Total coliforms (82% of residences sampled had Unacceptable concentrations in their tap water). The Unacceptable total coliforms results were found in Study Areas 5, 6, 7, and 8. However, the majority of the Unacceptable results (i.e., 45 of the 57 residences sampled [79%]) were found in Study Areas 5 and 8. One possible explanation for these results is the lack of routine disinfection of household tap water holding/storage tanks that are used to maintain the water supply/pressure in residences. If these holding/storage tanks are open at the top, animals and other material can enter the tank and may result in an unsanitary condition.
 - Total dioxins/furans [2,3,7,8-TCDD TEQs] were detected in tap water at concentrations exceeding the RSL but below the PHE's risk management criteria for Unacceptable risk in 8 of the 57 residences sampled (14%). It exceeded the RSL in Study Area 5 and 8.
- **Soil** – Two (2) of 184 residences (1%) sampled for soil had Unacceptable risks due solely to COCs in soil. Total Carcinogenic PAHs (BaP TEQs) were responsible for the Unacceptable risks at both locations in Study Area 5. Remedial actions were implemented at both residences and the risks associated with exposure to soil were then considered Acceptable. Soil sampling was discontinued midway through Phase II because results from Phase I & Phase II samples indicated that soil contamination did not pose a significant human health risk.
 - **Soil Gas** – Forty-nine (49) of the 300 residences (16%) sampled for soil gas had Unacceptable risks due solely to COCs in soil gas. These results are dominated by the results from Phase II where 32 of 175 residences (18%) sampled for soil gas had Unacceptable risks due solely to COCs in soil gas. In contrast, only eight of 110 residences (7%) sampled for soil gas during Phase I had Unacceptable risks due solely to COCs in soil gas. However, this difference might be explained by the fact that active soil gas samples were collected during Phase II (i.e., TO-15/SUMMA Canisters) rather than the passive soil gas samples (i.e., Gore-Sorber®) that were collected during Phase I. As presented in Figure F-5, the majority of residences with

Unacceptable concentrations in soil gas were located in Study Area 8. There also was a cluster of Unacceptable soil gas results comprised of three residences located in Study Area 6 west of the Gricignano Support Site near the border with Study Area 7. The remaining study areas had very low frequencies of Unacceptable soil gas. Despite the low frequency in Study Area 1, it was difficult to explain the soil gas exceedances in this area because it was expected to have a high frequency of Acceptable soil gas results (based on the history of urban development, lack of open space which would typically discourage dumping of waste, and tap water results from Phase I of the PHE). In addition, Study Area 5 had two clusters of soil gas exceedances: (1) comprised of four residences located just south of Lago Patria, and (2) two residences located immediately north of the border with Study Area 1.

Chloroform and tetrachloroethene were responsible for the majority of the risks associated with soil gas. Twelve (12) of the 300 (4%) residences sampled had Unacceptable risks associated with chloroform in soil gas. The Unacceptable soil gas results for chloroform were distributed throughout four of the nine study areas (1, 5, 6, and 8). Twenty-eight (28) of the 300 (9%) residences sampled had Unacceptable risks associated with tetrachloroethene in soil gas. The Unacceptable soil gas results for tetrachloroethene were distributed throughout four of the nine study areas; there was a higher frequency of Unacceptable results attributable to tetrachloroethene in Study Areas 5, 6, and 8. The COCs benzene and ethylbenzene were less frequently associated with Unacceptable risks (2% and 1%, respectively), but were frequently detected at concentrations above the RSL but below the PHE's risk management criteria for Unacceptable risk (10% and 11%, respectively). Other COPCS, such as 1,4-dichlorobenzene, carbon tetrachloride, hexane, and trichloroethene were infrequently detected in soil gas at Unacceptable concentrations. While the health risks at the specific locations where these COPCS were detected in soil gas were of concern, they were not included in this discussion because the focus of this discussion was on region-wide impacts rather than impacts at individual residences.

Residences in the proximity of residences that were sampled for soil gas and were considered Acceptable were more likely to have Acceptable results than residences that were located near residences with Unacceptable results. However, it was not possible to quantify the probability of finding Acceptable versus Unacceptable residences based solely on soil gas results in the Campania Region because, unlike tap water results, the distribution of Unacceptable soil gas results appeared to be more random, and not correlated with a specific geographic area. Therefore, based on the results of the PHE, it was not possible to make definitive recommendations regarding which study areas were more or less of a concern to human health based on exposure to COPCS in soil gas alone.

- **Ambient Air:** *Note: Incremental risks could not be calculated for ambient air because background concentrations were not available for Naples, Italy (see Section 4.2 in the main report). Therefore, only total risks could be calculated. The following information is based on total risks.* Key findings of the year-long ambient air sampling and monitoring program, presented in Tables F-14, F-15 and F-16, include the following:
 - 1,2-Dibromo-3-chloropropane contributed the majority of the CCEF (average of 80%) for the nine study areas. The COC-specific CEF ranged from 397 to 727. 1,2-Dibromo-3-chloropropane was not included in the USEPA's 2007 Air Toxics Database so the ambient air concentrations from the PHE could not be compared with typical urban ambient air from the United States.
 - Acrolein contributed the majority of the CNCEF (average of 95%) for the nine study areas. The maximum NCEF (247) calculated for Study Area 7 was greater than the NCEF calculated for acrolein in typical urban air in the USEPA's 2007 Air Toxics Database (29). Acrolein also contributed the majority of the NCEF for typical urban air in the United States (average of 89%).
 - 1,2-Dichloropropane contributed an average of 3.5% to the cancer risk and 1.1% to the noncancer risk in the nine study areas.
 - The six other COCs contributed an average of less than two percent each to the cumulative cancer and noncancer risk for the nine study areas.
 - EPCs for total dioxins/furans varied significantly among study areas. Study Areas 6, 8, and 9 were the only study areas where the COC-specific CEF exceeded 10.
 - Arsenic EPCs were less than the EPC in typical urban air in the USEPA's 2007 Air Toxics Database in all study areas except for Study Area 3 where the COC-specific CEF was 16. Slightly elevated arsenic concentrations in Study Area 3 could be associated with more volcanic activity in the area.
 - The maximum CEF for benzene was detected in Study Area 8 at a concentration of 68, which was approximately 10 times higher than the CEF for typical urban air in the U.S. (i.e., 5.2). The CEFs for benzene in the other eight study areas were less than 10.
 - With the possible exception of total dioxins/furans in Study Areas 6, 8, and 9, no obvious trends were indicative of localized concentrations that might be associated with trash burning, trash dumping, or other point and non-point sources. Typically, there was not a significant difference in EPCs between study areas for the COCs, indicating that the concentrations represented typical urban air in the Campania Region.
 - 1,2-Dibromoethane and formaldehyde together contributed to 65% of the CCEF in the USEPA's 2007 Air Toxics Database (USEPA, 2007a) but were not significant contributors to the ambient air risk in the nine study areas (6%).

Cumulative risks in the nine study areas exceeded the cumulative risks for typical urban air calculated from the USEPA's 2007 Air Toxics Database (USEPA, 2007a). However, because some constituents (including 1,2-dibromo-3-chloropropane, the major cancer risk driver in the Campania Region) did not have corresponding values in the USEPA's 2007 Air Toxics Database, it was not possible to determine whether or not the cumulative ambient air risks in the Campania Region would have exceeded the risks from typical urban air in the U.S. The risk-driving COPCs for cancer risks based on the USEPA's 2007

Air Toxics Database (i.e., 1,2-dibromoethane and formaldehyde) together contributed to 65% of the typical urban air CCEF. These constituents were not significant contributors to cancer risks in the nine study areas. For a more complete summary of the year-long ambient air sampling and monitoring program, please see the *Ambient Air Quality and Meteorological Summary Report for the Period July 9, 2008 through July 8, 2009* (Tetra Tech, 2010).

Phase II	30	22	14	14	33	30	24	34	8	209
Total:	134	36	21	21	128	70	48	146	11	615

Notes:

Six hundred fifteen samples were collected from 543 residences during the PHE. Seventy-two of the residences were sampled (and re-sampled) during multiple sampling events (for a total of 615 samples). In most cases, the 72 residences were only re-sampled for media that were not sampled during previous sampling events.

Notes:
0.0 = Value is less than 0.1
-- = Value is zero or samples were not collected for that medium
CCEF - Cumulative Cancer Exceedance Factor
CNCEF - Cumulative Noncancer Exceedance Factor
Inh. - Inhalation
Ing. - Ingestion
Shaded cells indicate residence is Unacceptable based on RSL - Regional Screening Level
USMCL - United States Maximum Contaminant Level

⁽¹⁾ A vapor attenuation factor of 0.1 was applied in all instances to evaluate soil gas with the exception of multi-story residences that had a subsurface ventilated garages (i.e., podium-style construction) or apartment-type dwellings where the resident is above the ground floor of the structure (i.e., the resident lived on the second floor or higher, assuming that the first floor is the ground floor of the building). In these instances a multi-story attenuation factor was applied as described in Appendix B
⁽²⁾ Ing.+Inh. exposure scenario for residences assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice
⁽³⁾ Inh. Only exposure scenario for residences assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice
⁽⁴⁾ Ing.+Inh. exposure scenario for residences (total cumulative exceedance factor based on tap water, soil, and soil gas) assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice.
⁽⁵⁾ Inh. Only exposure scenario for residences (total cumulative exceedance factor based on tap water, soil, and soil gas) assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice.
⁽⁶⁾ Excluding constituents that are present at concentrations similar to those found in the environment (e.g., inorganic elements except for lead, copper, and thallium)
⁽⁷⁾ For explanation of the PHE Risk Management Categories see Section 4.3.
(i.e., dibromochloromethane, chloroform, and bromoform) using the THM USMCL rather than individual RSLs. The tap water concentration of THMs was less than the total THMs USMCL, therefore the risk at this location is considered Acceptable.
⁽⁸⁾ Residence is located outside of study area boundaries. It was included with the study area it was nearest to for analyses purposes.
⁽⁹⁾ Residence # 1877 was deemed inconclusive for the Ing. + Inh. exposure scenario due to a speciation data gap for radioactive chemicals, see Section 5.2.8

Total – Ingestion+Inhalation ⁶	2	0.11 – 3.9	0.11 – 53.4	<ul style="list-style-type: none"> ▪ Tap Water RSLs (2) ▪ Tap Water USMCLs⁸ (1) ▪ Soil (0) ▪ Soil Gas (0) 	Public Water Supply <ul style="list-style-type: none"> ▪ 4-Chloroaniline ▪ Lead ▪ Uranium ▪ Total Trihalomethanes ▪ Total Dioxins/Furans (2,3,7,8-TCDD TEQs) Soil <ul style="list-style-type: none"> ▪ Total Carcinogenic PAHS (BaP TEQs) Soil Gas <ul style="list-style-type: none"> ▪ Benzene ▪ Chloroform ▪ Ethylbenzene ▪ Hexachlorobutadiene ▪ Tetrachloroethene
Total – Inhalation Only ⁷	0	0.002 – 0.11	1.3 – 8.8	<ul style="list-style-type: none"> ▪ Tap Water RSLs (0) ▪ Tap Water USMCLs⁹ (0) ▪ Soil (0) ▪ Soil Gas (0) 	Soil <ul style="list-style-type: none"> ▪ Total Carcinogenic PAHS (BaP TEQs) Soil Gas <ul style="list-style-type: none"> ▪ Benzene ▪ Chloroform ▪ Ethylbenzene ▪ Hexachlorobutadiene ▪ Tetrachloroethene

Notes:

¹For explanation on the PHE Risk Management Categories, see Section 4.3

²An NCEF of one is equivalent to a hazard index of one

³A CEF of 10 is equivalent to a cancer risk of 1×10^{-5} or one in 100,000

⁴Media that have a CNCEF greater than one or a CCEF greater than 10 or tap water concentrations that exceed the USMCL and the associated number of residences

⁵Constituents that have exceedance factors greater than one (i.e., concentration was greater than RSL)

⁶Assuming that tap water **IS** used for drinking, cooking, brushing teeth, and making ice

⁷Assuming that tap water **IS NOT** used for drinking, cooking, brushing teeth, and making ice

⁸Exceedances of chemical or microorganism USMCLs

⁹Exceedances of microorganism USMCLs only

Notes:

-- = Constituent was not detected at this location.

Shaded cells indicate where the exposure point concentration exceeded the 2007 USEPA Air Toxics Ambient Air Concentration
⁽¹⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level was, "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

⁽²⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level was, "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

⁽³⁾ This facility is located within Study Area 1 but data collected from this facility was used to evaluate air for Study Area 4.

⁽⁴⁾ Trans-1,4-Dichloro-2-Butene was only detected in 1 of 52 (1.92%) samples analyzed in Study Area 5 and was only detected in 1 of 455 (0.2%) ambient air samples from all nine study areas. The single detection was observed in a sample from residence #1756 located on the Italian economy and is not considered representative of the ambient air in Study Area 5. Therefore, trans-1,4-dichloro-2-butene was not evaluated further in the SRE for exposures associated with ambient air.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

TOTAL⁽⁵⁾:				159.55	33.12		94.09	74.96

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

⁽¹⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

⁽²⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

⁽³⁾ This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

⁽⁴⁾ These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

⁽⁵⁾ These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

TOTAL⁽⁵⁾:				159.55	33.12		104.03	142.32

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatarant/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatabart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Table F-16: Constituents of Concern Identified for Ambient Air

COCs ⁽¹⁾	Typical Urban Air (2007 USEPA Air Toxics Database) ⁽²⁾			Summary of CEFs and NCEFs for the Nine Study Areas									
				Minimum and Maximum CEFs (NCEFs)				Ratio of Max CEF to CEF for Typical Urban Air or (Ratio Max NCEF to NCEF for Typical Urban Air)	Contribution to CCEF or CNCEF				
	EPC	CEF	NCEF	Min CEF (NCEF)	Location of Minimum	Max CEF (NCEF)	Location of Maximum		Average % of Naples Air CCEF	Average % of Naples Air CNCEF	% of U.S. Air CCEF	% of U.S. Air CNCEF

Total Dioxin/Furans (2,3,7,8-TCDD TEQs)	N/A	N/A	N/A	0.6	Study Area 2	39.6	Study Area 6	N/A	1.6%	0.01%	N/A	N/A	

Notes:

-- = Constituent was not detected in at least one study area.

N/A = Data were not available for this constituent in the 2007 USEPA Air Toxics Database.

⁽¹⁾ COC - Constituent of Concern with EPCs resulting in CEF greater than 10 or NCEF greater than one in at least one study area and with an EPC greater than the EPC for typical urban air (2007 USEPA Air Toxics Database)

⁽²⁾ See Table 4-19 and Appendix F for explanation of the development of EPCs using the 2007 USEPA Air Toxics Database.

SCREENING AND SPECIATION OF RADIONUCLIDES IN TAP WATER

1.0 INTRODUCTION

The purpose of this appendix is to provide a general description of the approach used in the investigation to screen and evaluate tap water samples for radionuclides and to summarize the results of the analyses. In general, drinking water sources throughout the world contain low levels of radionuclides from naturally occurring sources such as uranium, radium, and potassium that are commonly present in soil and rock. These naturally occurring radionuclides can dissolve in groundwater and surface water and as result can be found in drinking water supplies. There is also the potential for drinking water to contain man-made radionuclides, or enhanced concentrations of natural radionuclides, in locations near sources such as nuclear power plants or uranium and phosphate mines. Radionuclides are not generally present in drinking water supplies in concentrations that could impact human health, but because the sources of potential contamination in water in the Naples area are unknown, screening for radionuclides was included in both Phase I and Phase II of the Public Health Evaluation (PHE). It is important to recognize that none of the tap water samples collected as part of the (ETSA) was found to contain radionuclides in excess of applicable United States Environmental Protection Agency (USEPA) Maximum Contaminant Levels (USMCLs).

Water samples collected during Phase I of the PHE (i.e., tap water collected from private wells, the public system, and water from irrigation sources) were analyzed for gross-alpha and gross-beta activity. During the Phase II investigation, the gross activity measurements were compared to screening criteria to determine whether radionuclide speciation was required to support the risk assessment. Attempts were made to return to residences sampled during the Phase I investigation that had gross radiation activities greater than the screening criteria. The process used to evaluate gross-activity results is summarized below and described in detail in Attachment A of this appendix, Volume I: Phase II ETSA (Tetra Tech, 2010), and the ETSA Quality Assurance Project Plan (QAPP [Tetra Tech, 2008]). Section 4 in the main body of this report (Phase I & II Screening Risk Evaluation) describes how risks were calculated for exposure to radionuclides via tap water ingestion.

Risk management decisions for the PHE have been based on an incremental screening risk process. For radionuclides, the incremental screening risk is defined for this project to be the total screening risk minus the screening risk attributable to potassium-40, and other naturally occurring radionuclides.

2.0 RADIONUCLIDE SCREENING AND SPECIATION PROCESS

A two-step screening approach was used to evaluate the incremental screening risks associated with radionuclides observed in tap water samples. The process is described below and illustrated in the flow charts provided in Attachment G-1:

Step 1

All water samples collected during Phase I and Phase II were analyzed for gross-alpha and gross-beta activity. Phase 1 samples exceeding the project screening criteria, defined as the United States Safe Drinking Water Act (SDWA) USMCL for gross-alpha activity (15 picocuries per liter [pCi/L]) and the SDWA screening level for gross-beta activity (50 pCi/L), were selected for resampling during the Phase II sampling evolution. The 50 pCi/L screening criterion includes all beta-emitting radionuclides, including those that would typically be subtracted in order to show compliance with the SDWA. It was selected for the initial screening of the Phase I samples because there was insufficient information to allow a lower screening concentration to be used, as was done for the Phase II samples and the Phase I resamples.

The Phase II samples and the Phase I resamples were analyzed for gross-alpha and gross-beta activity, total uranium, and naturally occurring potassium-40. Potassium-40 is a beta-emitting radionuclide that is naturally present in any material containing potassium, including most water and foods, and is not regulated by the SDWA. Potassium-40 is not considered to be a health hazard because it does not accumulate in the body. The body maintains an equilibrium concentration of potassium and the fraction of potassium-40 present remains unchanged from what is found in nature. The potassium-40 present in water samples will contribute to the gross-beta activity and must be subtracted from a gross activity measurement in order to obtain an estimate of the concentrations of regulated radionuclides. For these samples, the screening criteria were defined as 15 pCi/L for gross-alpha activity and 8 pCi/L for gross-beta activity (minus the contribution from potassium-40). The 8 pCi/L screening criterion is based on the activity-concentration equivalent of the SDWA standard for beta-emitting radionuclides. The USMCL for beta-emitting radionuclides is based on a radiation dose of 4 millirems per year (mrem/y), effective dose equivalent. A dose cannot be derived from the gross-activity concentration without knowing the radionuclide of concern. For this investigation, the strontium-90 was selected as the radioisotope of concern because it is the most restrictive man-made beta emitting radionuclide that is likely to be found as an environmental contaminant. The strontium-90 concentration equivalent to 4 mrem/y is 8 pCi/L.

If the measured gross-activity concentrations were less than their respective screening criteria, then no additional evaluation was required and the radionuclide concentrations were considered Acceptable per the risk management framework used in the PHE for alpha-emitting radionuclides (other than uranium) and beta-emitting radionuclides. If the concentrations exceeded the screening criteria, then the samples

were subjected to additional radionuclide-speciation analyses in order to determine whether radionuclides would be included in the determination of the total screening risks. If there was insufficient sample for the speciation analyses, the location was resampled, where possible.

Step 2:

If gross activity exceeded the screening criteria as described above, the radionuclide content was speciated as follows:

- A. The gross-alpha USMCL excludes uranium, so a determination of whether a sample result in excess of 15 pCi/L was considered an exceedance required analyzing the speciated sample for uranium and subtracting its contributions. Whenever the sample results exceeded the screening criterion for gross-alpha activity, those samples were then further analyzed for uranium, radium-226, and radium-228. Resampling was performed, where possible, at locations where there was insufficient sample volume for additional analyses. Radium-228 is a beta emitting radionuclide and does not contribute to the gross-alpha activity, but the SDWA defines the radium USMCL as the combined radium-226 and radium-228 concentrations. Consequently, samples with gross-alpha activity exceeding the screening criterion were required to be analyzed for radium-228 as well as radium-226. The constituent-specific results for gross-alpha, uranium, radium-226, and radium-228 for the re-sampling would be compared to the USMCLs and regional screening levels (RSL) for these constituents. The speciated results for uranium and radium-226/228 would then represent the incremental screening risks.

- B. Gross Beta Activity: Samples were analyzed for gross-beta activity and total potassium, which was used to calculate the activity concentration of the potassium-40. For each sample, the potassium-40 concentration was subtracted from the gross-beta activity and the result was then compared to the calculated-activity equivalent of the strontium-90, USMCL of 8 pCi/L. All samples with a gross-beta concentration (after subtracting potassium-40) exceeding 8 pCi/L were analyzed for strontium-90 and radium-228. Radium-228 concentrations are subtracted from the gross-beta concentration for screening because it is naturally occurring and the USMCL for beta emitters is limited to anthropogenic radionuclides. Then the strontium-90, potassium-40, and radium-228 concentrations were subtracted from the gross-activity concentration and the result was compared against the 50 pCi/L screening criterion. Corrected gross-beta activity greater than 50 pCi/L or detectable strontium-90 concentrations exceeding the USMCL or RSL would be included in the incremental screening risks.

3.0 SUMMARY OF RADIONUCLIDE SCREENING AND SPECIATION RESULTS

Table G-1 summarizes the water samples analyzed and the exceedances of the established project radionuclide screening criteria. During the entire investigation, 646 water samples, including duplicates, were analyzed for gross-alpha and gross-beta activity. Gross-alpha activity was detected in 214 of these samples. However, tap water samples from only two residences located on the Italian economy exceeded the project gross-alpha activity screening criterion of 15 pCi/L. Gross-beta activity was detected in 358 samples. The gross-beta minus potassium-40 screening criterion of 8 pCi/L was exceeded for only 58 residences located on the Italian economy.

The 58 residences on the Italian Economy with radiological activity exceeding the initial gross-alpha or gross-beta screening criteria were identified as candidates for further analysis for speciation of the radionuclides. Speciation analyses could not be completed for 22 of those locations because there was insufficient volume of the initial samples and logistical difficulties precluded gaining access to the residences to collect additional tap water. Table G-2 presents summary explanations of why re-sampling could not be accomplished at these 22 residences. The two locations with gross-alpha screening exceedances were among the locations where access could not be gained for additional sample collection. Because of the inability to collect samples needed for speciation analyses at the 22 residences listed in Table G-2, it was not possible to reach any conclusions about the effect of the radionuclide concentrations in the tapwater on the acceptability of these residences. However, because of other data available, the speciation data gaps do not have a significant effect on the PHE. The data gaps are discussed in detail in Section 4.0 of this report.

For the 37 locations where the speciation process could be applied (either because sufficient sample volume was available for the speciation process, or tap water could be re-sampled), the results for the beta-emitting speciated radionuclides (strontium-90 and radium-228) were all less than the detection limit, and the gross-beta minus potassium-40 concentrations were all less than the screening criterion of 50 pCi/L. Consequently, the radionuclide incremental screening risks at these 37 residences were all considered Acceptable. There was not a single incidence where a property was determined to be Unacceptable based on a radiological issue.

4.0 EFFECT OF DATA GAPS FOR SPECIATED RESULTS

Although it was not possible to obtain samples for re-analysis at all locations that exceeded the screening criteria, project risk-assessment personnel have concluded that the resultant data gaps do not have a significant effect on the PHE. This is primarily because 20 of the 22 locations for which speciation samples could not be collected (see Table G-2) were designated as having Unacceptable ingestion+inhalation and inhalation-only risks because of concentrations of other chemicals. That

designation would not be changed by the addition of risk from potentially-elevated radionuclide concentrations.

One location (1877 – A Pre-Lease location) potentially could be affected by elevated radionuclide concentrations. That location had a gross-beta result (after subtracting the potassium-40 contribution) that exceeded the 8 pCi/L criterion. In accordance with the QAPP (Tetra Tech, 2008), it should have been analyzed for strontium-90 and radium-228. Unfortunately, there was insufficient sample volume available from the initial sample for the speciation analyses and project personnel were unsuccessful in contacting the tenant to collect an additional sample. This location was designated as Acceptable for (ingestion+inhalation) of tap water and was also Acceptable for (inhalation-only) tap water for constituents other than radionuclides. Because of the speciation data gap, the effect of radionuclides could not be evaluated and so this location was characterized as Inconclusive for the ingestion+inhalation of tap water pathway. The location was still designated as Acceptable for the inhalation of tap water pathway because the radionuclides of interest are primarily a concern to human health through ingestion, not inhalation.

Although it is not possible to reach definitive conclusions where data gaps exist, consideration of the complete data set (presented by study area in Table G-3) provides a level of confidence that radionuclide concentrations are not likely to be sufficiently elevated to result in an Unacceptable risk at location 1877. The strontium-90 results are reasonable indicators of the presence of anthropogenic radionuclides. The strontium-90 results for the samples from the 37 speciated locations were all less than the detection limit, which would indicate that there is no significant source of anthropogenic radionuclides in the region and it is unlikely that there would be a localized source that would affect location 1877 alone. Similarly, none of the speciated samples exhibited elevated concentrations of radium-228, which indicates that regional radium-228 concentrations are not high enough to present a risk, and a localized source affecting only location 1877 is unlikely. From this, it is reasonable to conclude that if it had been possible to complete speciation analyses for all 58 indicated residences, the results for the 22 non-speciated homes would likely have been consistent with the results of the speciated locations, none of which identified any radiological exceedances warranting any further action.

5.0 URANIUM IN DRINKING WATER

In addition to the gross-alpha and gross-beta analyses, a total of 646 samples were analyzed for total uranium. The uranium results were used in determining the need for speciation, and the results of the uranium analyses were also compared directly against the applicable RSL and the USMCL. As previously stated, uranium is a naturally-occurring, radioactive element that is commonly found in water supplies. Except for some locations near uranium mining or processing facilities, uranium in drinking water is almost always attributable to naturally-occurring background sources. However, because uranium is radioactive, its ingestion presents a cancer risk and (depending on the concentration) it may

harm the kidneys if prolonged exposure occurs. Because of the risks and common occurrence, the USEPA has established a USMCL of 30 micrograms per liter (ug/L) for uranium in public drinking water supplies. In establishing the USMCL, the USEPA considered a number of factors, including the radiation risk, the kidney toxicity, the feasibility of achieving reduced uranium concentrations and the cost effectiveness of removal. The USEPA concluded that it would not be feasible to reduce uranium concentrations below 20 ug/L. As a result, the USEPA established a 30 ug/L USMCL as an achievable concentration considered to be protective of human health, and having an associated cancer risk that is within the target range of 1E-04 and 1E-06 used in developing the U.S. drinking water standards. To be consistent with the SRE's evaluation of other constituents, observed uranium concentrations were compared to both the USMCL and an RSL of 1.62 ug/L. However, the RSL is based on a cancer risk of 1E-06, without addressing the other factors considered by the USEPA. Also, the RSL is comparable to the mean uranium concentrations found in U.S. drinking water supplies. For the Naples SRE, the uranium RSL was used to calculate the incremental screening risk associated with drinking water because site-specific natural background concentrations of uranium in tap water were not available. The RSL for the PHE is very conservative and is approximately 19 times lower than the uranium concentration that would be considered Acceptable (i.e., the USMCL of 30 ug/L) in drinking water supplies in the U.S.

Uranium concentrations in all of the tap water samples collected during this investigation were less than the USMCL of 30 ug/L. Water samples from 191 residences exceeded the RSL of 1.62 ug/L. All residences for which uranium concentrations exceeded the RSL were identified as Unacceptable because of the presence of other chemical constituents. Therefore, no properties evaluated in this investigation were found to be Unacceptable based on a radiological issue alone.

Table G-1
Summary of Radionuclide Screening and Speciated Results

Radiological Parameter	Number of Samples Analyzed	Number of Detected Results	Project Screening Criterion	Number of Residences with Samples Exceeding Screening Criterion
Gross-Alpha	646 ^(a)	214	15 pCi/L	3 ^(b)
Gross-Beta	646 ^(a)	358	8 pCi/L	58 ^(c)
Speciated Analyses	37 ^(d)	0	Radium-226/228 – 5 pCi/L	3 (Radium-228)
			Strontium-90 – 8 pCi/L	0
			Other beta/photon emitters – 50 pCi/L	0

Notes:

^aTotal number of samples analyzed includes tap water, irrigation water, samples from U.S. Government-related facilities, and field duplicates.

^bGross-Alpha samples from three locations exceeded the screening criterion but only two were from private residences located on the Italian Economy. The other sample with a screening exceedance was an irrigation water sample from Parco Le Ginestre.

^cGross-Beta samples exceeded the screening criterion at 58 residences located on the Italian Economy. At two of these locations, samples also exceeded the gross-alpha activity screening criterion.

^dAccording to the provisions of QAPP and Radiological Screening Procedure, 58 locations should have been reanalyzed for speciation but speciation was possible for only 37 residences because of logistical difficulties associated with gaining access to 22 residences to collect additional tap water samples (see Table G-2). This count (i.e., 22) includes one residence, #1614, where the original gross-beta sample result exceeded 50 pCi/L but water source was blended; re-sampled as pre-lease location on 10/17/08 but plumbing was changed to public water source and gross-beta was < 8 pCi/L after K-40 correction; outside well was re-sampled on 5/23/09 (sample named 1614IW - speciation results were not detected).

Table G-2

Reasons Residences Were Not Re-sampled for Speciation of Radionuclides

Locations with Exceedance of the Gross Activity Screening Level	Water Source	Reason Residence Was Not Re-sampled for Speciation of Radionuclides
0217	Well	Landlord declined access
0238	Well	Home has been changed to public water source; well is no longer accessible.
0250	Well	Home has been changed to public water source; well has been removed.

Notes:

-- = Chemical was not detected at this location.

Qualifiers:

Blank or no qualifier. The analyte was detected and the concentration is presented in the result column.

U = The analyte was not detected. The reporting limit is presented as the result.

J = The result is an estimated concentration.

Shaded and bold values are instances where the water concentration exceeds the USMCL

Evolution and Summary of Radiological Screening Levels Used for Tap Water in the Naples Environmental Testing Support Assessment

BACKGROUND

The Navy/Marine Corps Public Health Center (NMCPHC) is conducting an Environmental Testing Support Assessment (ETSA) in the Campania region of Naples, Italy. This assessment was designed and intended to be a screening-level risk evaluation, which was part of a broader Public Health Evaluation (PHE). The objective was to evaluate potential health risks to United States (U.S.) Department of Defense (DoD) and civilian personnel living in this region. The ETSA was initiated in response to concerns about improper hazardous and municipal waste disposal practices that have been occurring in this region. These waste disposal practices have the potential to release contaminants to the environment, thus affecting the health of nearby residents and workers.

Most drinking water sources have very low levels of radioactive contaminants ("radionuclides"), most of which are naturally occurring, although contamination of drinking water sources from man-made nuclear materials can also occur. Most radioactive contaminants observed in drinking water are at levels that are low enough to not be considered a public health concern.

To protect public health, the U.S. Environmental Protection Agency (EPA) has established standards for public drinking water supplies for several types of radioactive contaminants, which include combined radium-226/228 (5 picocuries per liter [pCi/L]); beta/photon emitters (4 millirems per year [mrem/yr]); gross alpha activity, excluding radium-226 and uranium (15 pCi/L); and uranium (30 micrograms per liter [$\mu\text{g/L}$]). These standards, or Maximum Contaminant Levels (MCLs), were adopted for the ETSA.

The ETSA is being completed in stages. The ETSA began with a pilot study, was followed by a Phase I study, and was subsequently followed by a Phase II study (started prior to the completion of the Phase I study). During the Pilot and Phase I studies, tap water samples were only evaluated for gross alpha and gross beta levels. During the Phase II study, the analytical parameters were expanded to include radiological speciation (i.e., measurement of key anions contributing to the overall radioactivity) if results were found to exceed the established screening values.

GROSS ALPHA EVALUATION FOR ETSA PILOT STUDY AND PHASE I

The gross-alpha MCL is 15 pCi/L, excluding uranium, which has a specific MCL. Under certain circumstances, a 15 pCi/L concentration may be used for screening purposes, and that concentration was selected for the ETSA sampling. For evaluation of Safe Drinking Water Act compliance in the U.S., it is customary to evaluate gross alpha activity using the results of four quarterly samples collected from a public drinking water system and compare the MCL to the results of the sample analyses to determine the next course of action. However, as the ETSA is a screening-level assessment, only one sample was collected at each property or location. Each tap water sample was submitted to a laboratory for gross alpha analysis using methods consistent with those used in the U.S. for drinking water evaluations.

GROSS ALPHA AND RADIOLOGICAL SPECIATION EVALUATION FOR ETSA PHASE II

The ETSA gross-alpha screening criterion is 15 pCi/L. If that criterion is not exceeded, then no additional evaluation is conducted at that property. If this criterion is exceeded, then the uranium, radium-226, and radium-228 concentrations are measured and compared to their MCLs. If any of those analyte-specific measurements exceed the applicable MCL, a human health risk assessment is conducted in accordance with the ETSA Phase II plan (see Attachment 1).

GROSS BETA EVALUATION FOR ETSA PILOT STUDY AND PHASE I

The MCL for total beta/photon emitters is 4 mrem/yr effective dose equivalent (EDE). This MCL is a dose value rather than a concentration value. A dose value could not be measured directly, so in practice it was necessary for all of the beta activity in a sample to be quantified and the dose calculated using an EPA approved method. To simplify the process, EPA allows use of a screening value of 50 pCi/L (total beta activity minus potassium-40 [K-40] beta contribution). Attachment 2 is an EPA quick reference guide to the evaluation of radionuclides in drinking water. The guide shows the use of this screening value as a means to determine whether sampling frequency should be increased or decreased for a U.S. public water system.

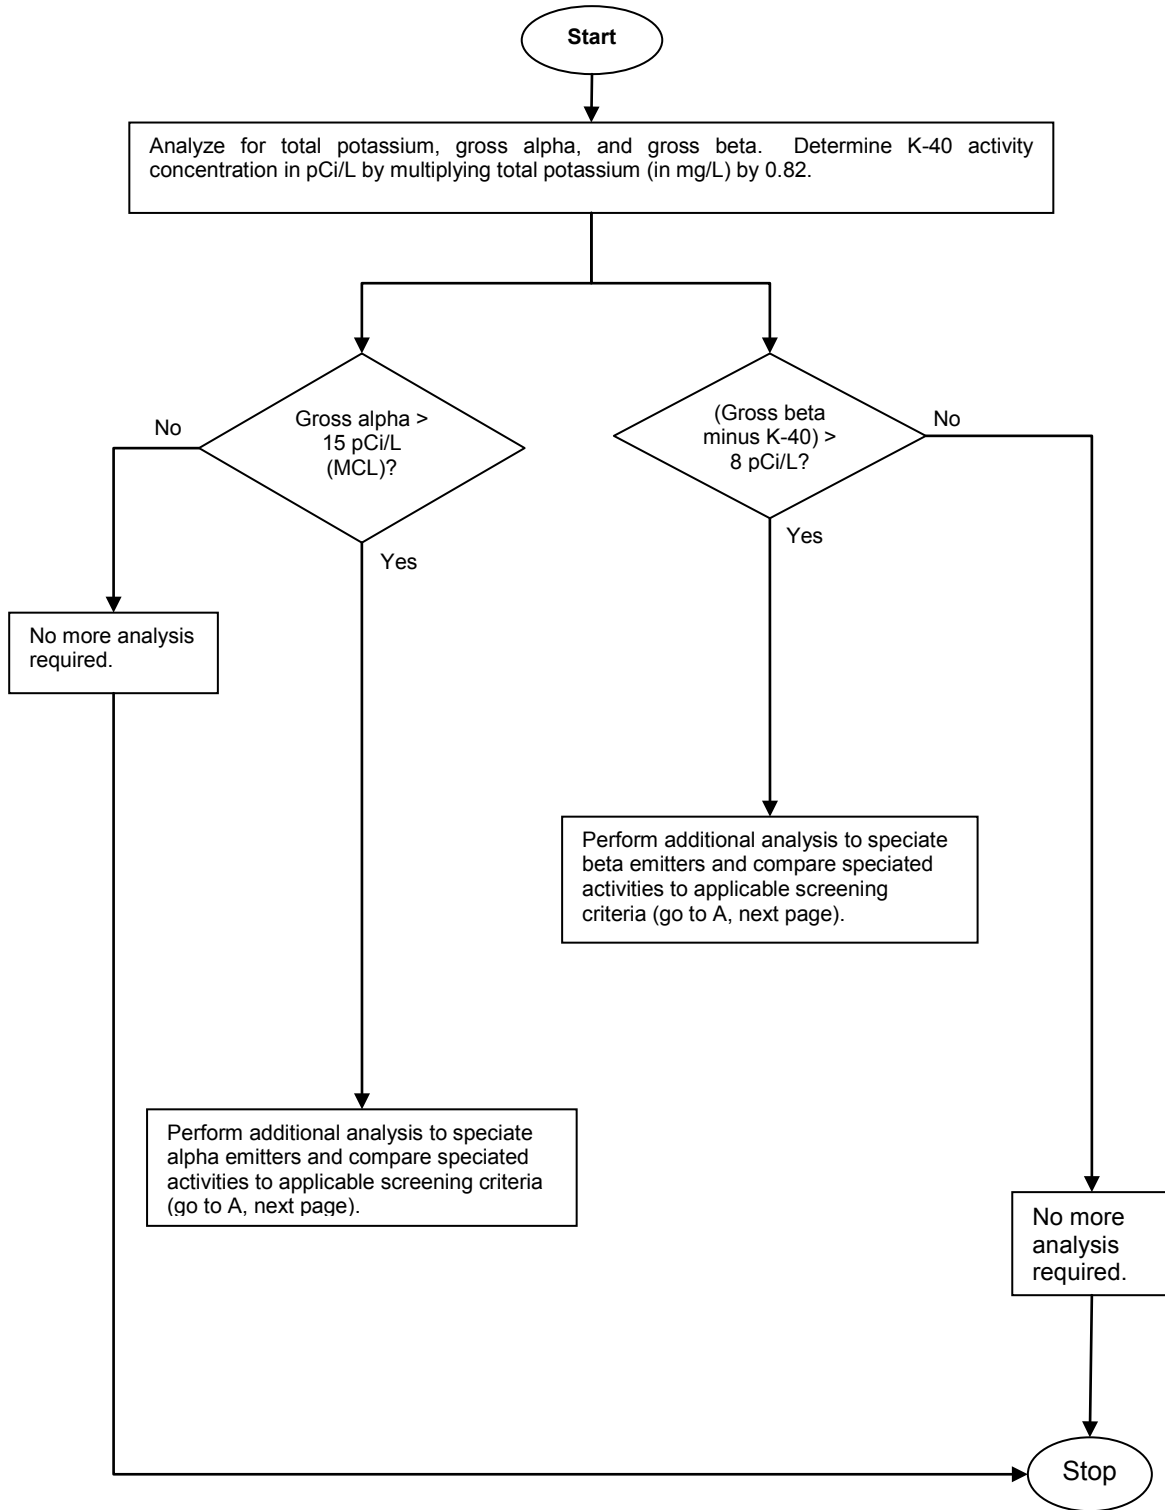

GROSS BETA AND RADIOLOGICAL SPECIATION EVALUATION FOR ETSA PHASE II

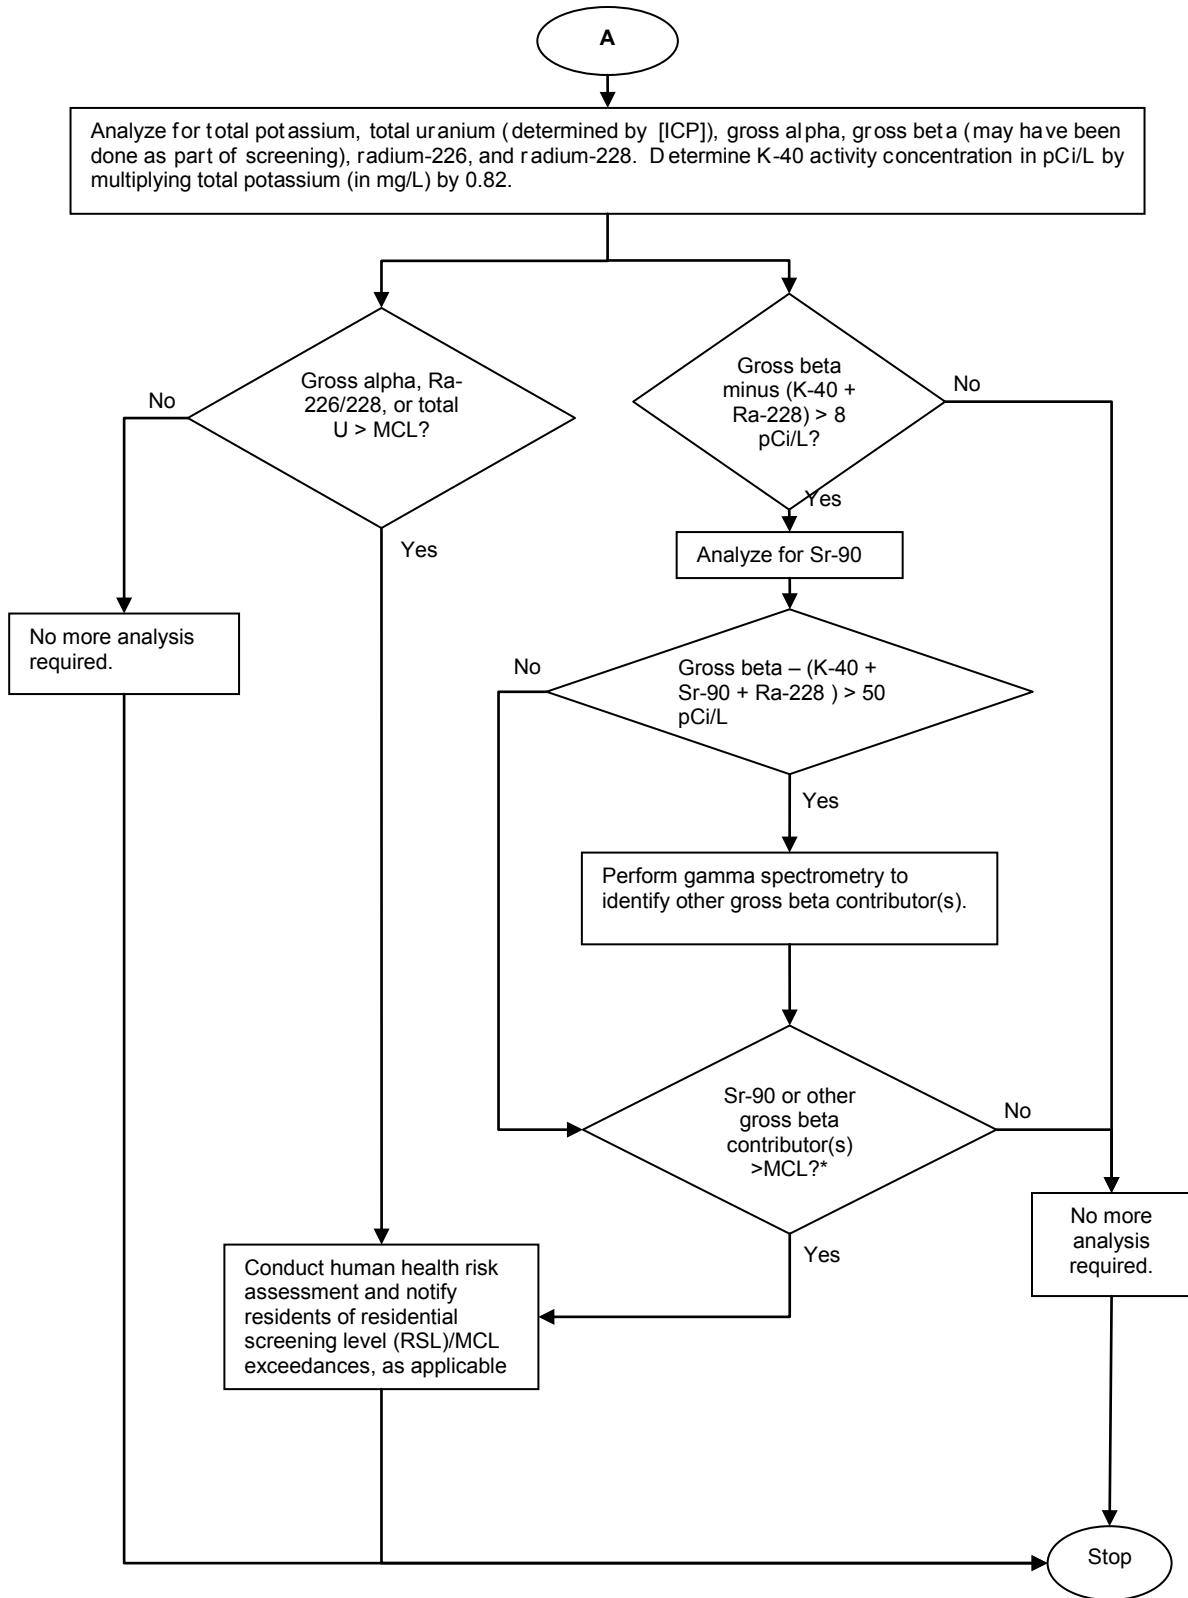

For the ETSA Phase II sampling, a screening value of 8 pCi/L (obtained after subtracting the beta contribution from K-40) was selected. K-40 is subtracted from the gross-beta before comparing against the screening criterion because it is a naturally occurring component of potassium, and is present in all water supplies and in most foods. Because it does not accumulate in the body, the body maintains K-40 in a state of equilibrium. The 8 pCi/L concentration is equivalent to the concentration of strontium-90 (Sr-90) that would result in a dose of 4 mrem/yr EDE, using the EPA approved methods and default parameters. Sr-90 was selected for determining the screening value because it is a radionuclide that could be present in drinking water supplies and yields the 4 mrem/yr dose limit at low concentration. Therefore, its use affords a conservative measure of protection for people exposed to the water.

If the gross beta measurement for a tap water sample collected at a property is less than or equal to 8 pCi/L after the contribution from K-40 is subtracted, no more investigation is conducted. If the 8 pCi/L is exceeded, the beta-activity contributions from radium-228, Sr-90, and other radionuclides are determined as necessary, and evaluated in accordance with the flowchart in Attachment 1. The investigation stops when one of the applicable criteria is satisfied. If the investigation has not stopped previously, the final test is whether the combined concentrations of beta-emitting radionuclides would result in a dose exceeding the 4 mrem/yr EDE MCL. If the calculated EDE is below the MCL, then the investigation stops, otherwise a human health risk assessment is conducted in accordance with the ETSA Phase II plan (see Attachment 1).

Attachment 1 – ETSA Tapwater Radionuclide Screening Process

*For comparison to 4 mrem/yr MCL, compute sum of fractions as described in U.S. Safe Drinking Water

Radionuclides Rule: A Quick Reference Guide

Overview of the Rule

Title	Radionuclides Rule 66 FR 76708 December 7, 2000 Vol. 65, No. 236
Purpose	Reducing the exposure to radionuclides in drinking water will reduce the risk of cancer. This rule will also improve public health protection by reducing exposure to all radionuclides.
General Description	The rule retains the existing MCLs for combined radium-226 and radium-228, gross alpha particle radioactivity, and beta particle and photon activity. The rule regulates uranium for the first time.
Utilities Covered	Community water systems, all size categories.

Public Health Benefits

Implementation of the Radionuclides Rule will result in . . .	Reduced uranium exposure for 620,000 persons, protection from toxic kidney effects of uranium, and a reduced risk of cancer.
Estimated Impacts of the Radionuclides Rule include . . .	Annual compliance costs of \$81 million. Only 795 systems will have to install treatment.

Regulated Contaminants

Regulated Radionuclide	MCL	MCLG
Beta/photon emitters*	4 mrem/yr	0
Gross alpha particle	15 pCi/L	0
Combined radium-226/228	5 pCi/L	0
Uranium	30 µg/L	0

*A total of 168 individual beta particle and photon emitters may be used to calculate compliance with the MCL.

Critical Deadlines & Requirements

For Drinking Water Systems

June 2000 - December 8, 2003	When allowed by the State, data collected between these dates may be eligible for use as grandfathered data (excluding beta particle and photon emitters).
December 8, 2003	Systems begin initial monitoring under State-specified monitoring plan unless the State permits use of grandfathered data.
December 31, 2007	All systems must complete initial monitoring.

For States

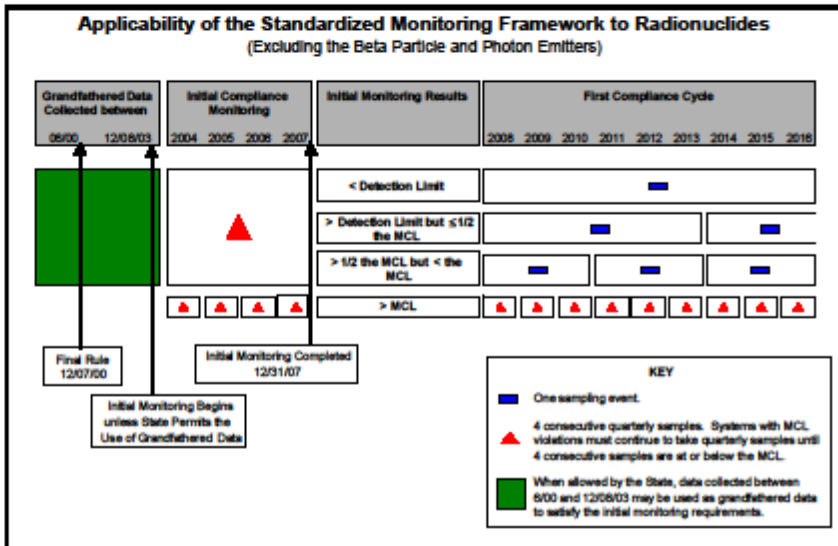

December 2000 - December 2003	States work with systems to establish monitoring schedules.
December 8, 2000	States should begin to update vulnerability assessments for beta photon and particle emitters and notify systems of monitoring requirements.
Spring 2001	EPA meets and works with States to explain new rules and requirements and to initiate adoption and implementation activities.
December 8, 2002	State submits primacy revision application to EPA. (EPA approves within 90 days.)

For additional information on the Radionuclides Rule

Call the Safe Drinking Water Hotline at 1-800-426-4791; visit the EPA Web site at www.epa.gov/safewater; or contact your State drinking water representative. EPA will provide radionuclide training over the next year.

Monitoring Requirements	
Gross Alpha, Combined Radium-226/228, and Uranium (1)	Beta Particle and Photon Radioactivity (1)
Initial Monitoring	
Four consecutive quarters of monitoring.	No monitoring required for most CWSs. Vulnerable CWSs (2) must sample for: <ul style="list-style-type: none"> Gross beta: quarterly samples. Tritium and Strontium-90: annual samples.
Reduced Monitoring	
If the average of the initial monitoring results for each contaminant is below the detection limit: One sample every 9 years.	If the running annual average of the gross beta particle activity minus the naturally occurring potassium-40 activity is less than or equal to 50 pCi/L: One sample every 3 years.
If the average of the initial monitoring results for each contaminant is greater than or equal to the detection limit, but less than or equal to one-half the MCL: One sample every 6 years.	
If the average of the initial monitoring results for each contaminant is greater than one-half the MCL, but less than or equal to the MCL: One sample every 3 years.	
Increased Monitoring	
A system with an entry point result above the MCL must return to quarterly sampling until 4 consecutive quarterly samples are below the MCL.	If gross beta particle activity minus the naturally occurring potassium-40 activity exceeds 50 pCi/L, the system must: <ul style="list-style-type: none"> Speciate as required by the State. Sample at the initial monitoring frequency.
(1) All samples must be collected at each entry point to the distribution system. (2) The rule also contains requirements for CWSs using waters contaminated by effluents from nuclear facilities.	
Grandfathering of Data	
When allowed by the State, data collected between June, 2000 and December 8, 2003 may be used to satisfy the initial monitoring requirements if samples have been collected from: <ul style="list-style-type: none"> Each entry point to the distribution system (EPTDS). The distribution system, provided the system has a single EPTDS. The distribution system, provided the State makes a written justification explaining why the sample is representative of all EPTDS.

ATTACHMENT H-1 – CHEMICAL FACT SHEETS

**This page has been left blank intentionally
to allow for double-sided printing.**

CHEMICAL FACT SHEET OVERVIEW

This appendix presents chemical fact sheets answering the most frequently asked health questions for the constituents of potential concern identified in the Naples, Italy Public Health Evaluation Phase I & II Screening Risk Evaluation. Fact sheets are presented for the following constituents:

- 1,1,1,2-Tetrachloroethane
- 1,1,2,2-Tetrachloroethane
- 1,2-Dibromo-3-Chloropropane
- 1,2-Dibromoethane
- 1,2-Dichloroethane
- 1,2-Dichloropropane
- 1,3-Butadiene
- 1,4-Dichlorobenzene
- 4-Chloroaniline
- Acetaldehyde
- Acrolein
- Acrylonitrile
- Arsenic
- Benzene
- Bis(2-ethylhexyl)phthalate
- Bromodichloromethane
- Bromoform and Dibromochloromethane
- Carbon Tetrachloride
- Chloroform
- Cobalt
- Copper
- Dieldrin
- Ethylbenzene
- Fecal Coliform and Total Coliforms
- Fluoride
- Formaldehyde
- Hexachlorobutadiene
- Hexane
- Lead
- Methyl tert-Butyl Ether
- Naphthalene
- Nitrate (measured as NO₃-)
- Tetrachloroethene
- Thallium
- Total Carcinogenic PAHS (BaP TEQs)
- Total Dioxins/Furans (2,3,7,8-TCDD TEQs)
- Total Trihalomethanes (Refer to chemical fact sheets for Dibromochloromethane, chloroform, bromoform, and Bromodichloromethane.)
- Trichloroethene
- Uranium
- Vinyl Chloride

ATTACHMENT H-1

CHEMICAL FACT SHEETS

**This page has been left blank intentionally
to allow for double-sided printing.**

This fact sheet was created from information presented in the National Library of Medicine Hazardous Substances Data Bank. This fact sheet answers the most frequently asked health questions (FAQs) about 1,1,1,2-tetrachloroethane. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: 1,1,1,2-tetrachloroethane is a chemical that is a byproduct associated with manufacturing other chemicals. Breathing high levels can cause drowsiness, loss of appetite, nausea, and headache. Long term exposure to 1,1,1,2-tetrachloroethane can cause liver, kidney, and/or central nervous system damage.

What is 1,1,1,2-tetrachloroethane?

1,1,1,2-tetrachloroethane is a colorless, dense, volatile liquid. It has been used in the past as a solvent, and also during the manufacturing of pesticides, bleaches, paints, and varnishes. Today, it is produced as a byproduct during the manufacture of 1,1,1-trichloroethane, 1,1,2-trichloroethane, and 1,1,2,2-tetrachloroethane.

What happens to 1,1,1,2-tetrachloroethane when it enters the environment?

- 1,1,1,2-tetrachloroethane volatilizes easily from water and soil and is present as a vapor in the atmosphere.
- It is degraded in the atmosphere by different chemical reactions.
- The potential for 1,1,1,2-tetrachloroethane to build up in aquatic organisms is low.

How might I be exposed to 1,1,1,2-tetrachloroethane?

- The general public is not expected to be exposed to significant amounts of 1,1,1,2-tetrachloroethane. It is not commonly found in drinking water, soil, or food.
- You may be exposed to 1,1,1,2-tetrachloroethane if you live near a hazardous waste site that contains it or near an industrial building where the chemical is used.
- If spills or accidents occur at work, exposure will likely occur through breathing in vapors or through skin contact.

How can 1,1,1,2-tetrachloroethane affect my health?

- Being exposed to low levels of 1,1,1,2-tetrachloroethane in the air can cause irritation in the eyes, skin, and respiratory tract.
- Breathing in high concentrations of 1,1,1,2-tetrachloroethane can cause drowsiness, lack of appetite, nausea, and headache.
- Liver, kidney, and central nervous system damage has been observed in animals orally exposed to low doses for a long time.

How likely is 1,1,1,2-tetrachloroethane to cause cancer?

- It is not known whether 1,1,1,2-tetrachloroethane causes cancer in humans.
- In laboratory experiments, 1,1,1,2-tetrachloroethane caused an increase in liver tumors in female mice but not rats.
- The International Agency for Research on Cancer (IARC) has determined that 1,1,2,2-tetrachloroethane cannot be classified as to its ability to cause cancer in humans, while the United States Environmental Protection Agency (USEPA) has determined that it is a possible human carcinogen.

How can 1,1,1,2-tetrachloroethane affect children?

Exposure of children to large amounts of 1,1,1,2-tetrachloroethane is assumed cause the same effects observed in adults (i.e. drowsiness, loss of appetite, nausea, headache).

How can families reduce the risks of exposure to 1,1,1,2-tetrachloroethane?

Exposure to high amounts of 1,1,1,2-tetrachloroethane is unlikely because the chemical is not used in household products.

Is there a medical test to determine whether I've been exposed to 1,1,1,2-tetrachloroethane?

There are no medical tests to determine whether you have been exposed to 1,1,1,2-tetrachloroethane.

Has the federal government made recommendations to protect human health?

- The USEPA has not established a maximum contaminant level (MCL) for 1,1,1,2-tetrachloroethane.
- The Occupational Safety and Health Administration (OSHA) has not established a permissible exposure limit for 1,1,1,2-tetrachloroethane.

Where Can I Get More Information? More information on the adverse effects of 1,1,1,2-tetrachloroethane can be obtained from your community or state health or environmental quality department.

This fact sheet answers the most frequently asked health questions (FAQs) about 1,1,2,2-tetrachloroethane. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: 1,1,2,2-Tetrachloroethane is a manufactured chemical that is no longer used much in the United States. Breathing high levels in a closed room can cause fatigue, vomiting, dizziness, and possibly unconsciousness. Breathing, drinking, or touching large amounts of 1,1,2,2-tetrachloroethane for a long period of time can cause liver damage, stomachaches, or dizziness. 1,1,2,2-Tetrachloroethane has been found in at least 329 of the 1,699 National Priority List (NPL) sites identified by the Environmental Protection Agency (EPA).

What is 1,1,2,2-tetrachloroethane?

1,1,2,2-Tetrachloroethane is a manufactured, colorless, dense liquid that does not burn easily. It is volatile and has a sweet odor.

In the past, it was used in large amounts to produce other chemicals, as an industrial solvent to clean and degrease metals, and as an ingredient in paints and pesticides. Commercial production of 1,1,2,2-tetrachloroethane for these uses has stopped in the United States. It presently is used only as a chemical intermediate in the production of other chemicals.

What happens to 1,1,2,2-tetrachloroethane when it enters the environment?

- Most 1,1,2,2-tetrachloroethane released to the environment eventually moves to the air or ground water.
- It does not attach to soil particles when released to land.
- When released to surface water, much of it will evaporate to the air while the rest may break down in the water.
- Breakdown of the chemical in the environment is slow; it takes about 1 year for half of the chemical to disappear from groundwater and 2 months in air.
- 1,1,2,2-Tetrachloroethane does not build up significantly in the bodies of fish or other organisms.

How might I be exposed to 1,1,2,2-tetrachloroethane?

- The general public is not expected to be exposed to significant amounts of 1,1,2,2-tetrachloroethane. It is not commonly found in drinking water, soil, or food.
- Higher concentrations have been found occasionally in private well water that may have been used for drinking.
- You may be exposed to 1,1,2,2-tetrachloroethane if you live near a hazardous waste site that contains it or near an industrial building where the chemical is used.
- Since production of the chemical has stopped, most workers would not be exposed to it.
- If spills or accidents occur at work, exposure will likely be by breathing in vapors or through skin contact.

How can 1,1,2,2-tetrachloroethane affect my health?

Most of the 1,1,2,2-tetrachloroethane that you may ingest or inhale will enter the bloodstream.

Breathing very high concentrations of 1,1,2,2-tetrachloroethane can rapidly cause drowsiness, dizziness, nausea, and vomiting. Most people recover from these effects once they are in fresh air. Breathing high levels of 1,1,2,2-tetrachloroethane for a long time can cause liver damage.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Drinking very large amounts of 1,1,2,2-tetrachloroethane can cause shallow breathing, faint pulse, decreased blood pressure, and possibly unconsciousness.

Liver damage has been observed in animals orally exposed to lower doses for a long time.

How likely is 1,1,2,2-tetrachloroethane to cause cancer?

It is not known whether 1,1,2,2-tetrachloroethane causes cancer in humans. In a long-term study, 1,1,2,2-tetrachloroethane caused an increase in liver tumors in mice, but not in rats.

The International Agency for Research on Cancer (IARC) has determined that 1,1,2,2-tetrachloroethane cannot be classified as to its ability to cause cancer in humans, while the EPA has determined that it is a possible human carcinogen.

How can 1,1,2,2-tetrachloroethane affect children?

Exposure of children to large amounts of 1,1,2,2-tetrachloroethane will probably cause the same effects observed in adults (i.e., fatigue, vomiting, dizziness, liver damage, stomachache). It is not known whether children are more or less susceptible to the effects of 1,1,2,2-tetrachloroethane than adults.

Some effects have been observed in animals born to females exposed to 1,1,2,2-tetrachloroethane during pregnancy. This occurred at exposure levels that were also toxic to the mothers.

How can families reduce the risks of exposure to 1,1,2,2-tetrachloroethane?

Exposure to high amounts of 1,1,2,2-tetrachloroethane is unlikely because the chemical is no longer used in household products.

If you have old household products (i.e., cleaners, degreasers, and paints) at home that contain 1,1,2,2-tetrachloroethane, make sure they are stored out of the reach of children.

Is there a medical test to determine whether I have been exposed to 1,1,2,2-tetrachloroethane?

There are no medical tests to determine whether you have been exposed to 1,1,2,2-tetrachloroethane. Urine and blood tests are available, but are common to several other types of chemicals and would not specifically indicate exposure to 1,1,2,2-tetrachloroethane.

Has the federal government made recommendations to protect human health?

The EPA has determined that exposure to 1,1,2,2-tetrachloroethane in drinking water at a concentration of 0.04 mg/L for up to 10 days is not expected to cause any adverse effects in a child.

The EPA has determined that lifetime exposure to 0.0003 mg/L 1,1,2,2-tetrachloroethane in drinking water is not expected to cause any adverse effects.

The Occupational Safety and Health Administration (OSHA) has set a limit of 5 parts per million (ppm) of 1,1,2,2-tetrachloroethane in air to protect workers during an 8-hour workday, 40-hour workweek.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about 1,2-dibromo-3-chloropropane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to 1,2-dibromo-3-chloropropane occurs mainly from drinking water or eating food that contains the chemical. At high levels, this chemical may cause damage to the male reproductive system. This chemical has been found in at least 10 of 1,314 National Priorities List sites identified by the Environmental Protection Agency.

What is 1,2-dibromo-3-chloropropane?

(Pronounced 1,2-dī'brō'mō-3-klôr ō prō'pān')

1,2-Dibromo-3-chloropropane is a manufactured chemical and is not found naturally in the environment. It is a colorless liquid with a sharp smell. It can be tasted in water at very low concentrations.

Some industries use it to make another chemical that is used to make materials that resist burning.

Large amounts of 1,2-dibromo-3-chloropropane were used in the past on certain farms to kill pests that harmed crops. Farmers in all states other than Hawaii stopped using this chemical in 1979. Hawaii stopped using it in 1985.

We do not know exactly how much of it is currently made or used by industry, but it is probably a small amount.

What happens to 1,2-dibromo-3-chloropropane when it enters the environment?

- Most of it that enters surface water evaporates into the air within several days or a week.
- It takes several months for it to break down in air.
- It doesn't stick to soil at the bottom of rivers, lakes, or ponds.

- In soil, some evaporates into the air, while small amounts may stay in the soil for several years.

How might I be exposed to 1,2-dibromo-3-chloropropane?

- Drinking water or eating food that contains the chemical.
- Breathing air or touching soil at or near agricultural areas where 1,2-dibromo-3-chloropropane was used in the past.
- Breathing air at hazardous waste sites where improper disposal methods were used.
- Working in an industry that uses 1,2-dibromo-3-chloropropane.

How can 1,2-dibromo-3-chloropropane affect my health?

The main effect from breathing high levels of 1,2-dibromo-3-chloropropane is damage to the male's ability to reproduce.

Studies on workers have shown that men may produce fewer sperm, produce sperm that results in more girl than boy babies, and eventually become unable to father children. It can also cause headaches, nausea, lightheadedness, and weakness in workers.

Animals breathing high levels of the chemical were not

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

able to reproduce and had damaged stomachs, livers, kidneys, brains, spleens, blood, and lungs. Breathing low to moderate levels also caused damage to the reproductive system.

The ability of people to reproduce was not affected by drinking water contaminated with low levels of 1,2-dibromo-3-chloropropane and there was no increase in the number of birth defects. Rats exposed to high levels did, however, have an increase in birth defects. It can also cause skin and eye damage from direct contact.

How likely is 1,2-dibromo-3-chloropropane to cause cancer?

The Department of Health and Human Services has determined that 1,2-dibromo-3-chloropropane may reasonably be anticipated to be a carcinogen.

Animal studies found cancer of the nose in animals exposed by breathing the chemical, cancer of the stomach and kidney in animals that ingested the chemical, and cancer of the stomach and skin in animals who had skin contact with the chemical.

We do not know if these same cancers would occur in people.

Is there a medical test to show whether I've been exposed to 1,2-dibromo-3-chloropropane?

Tests are available that measure the amount of 1,2-dibromo-3-chloropropane in exhaled air, blood, and samples of tissues from the body. These tests may require special equipment and they may not be available in your doctor's office.

Because exposure to this chemical lowers the number of sperm, we can count the number of sperm and blood levels of certain hormones in exposed men to determine whether harmful effects have occurred. However, these changes cannot tell the level or length of exposure to the chemical.

Has the federal government made recommendations to protect human health?

The Environmental Protection Agency (EPA) has set a limit of 0.2 parts of 1,2-dibromo-3-chloropropane per billion parts of drinking water (0.2 ppb). EPA requires that discharges or spills into the environment of 1 pound or more of 1,2-dibromo-3-chloropropane be reported. EPA banned the use of 1,2-dibromo-3-chloropropane as a pesticide in the United States in the early 1980s.

The Occupational Safety and Health Administration (OSHA) has set an occupational exposure limit of 1 part of 1,2-dibromo-3-chloropropane in one billion parts of air (1 ppb) for an 8-hour workday over a 40-hour workweek.

The National Institute for Occupational Safety and Health (NIOSH) currently recommends that workers breathe as little 1,2-dibromo-3-chloropropane as possible.

Glossary

Carcinogen: A substance that can cause cancer.

Ingesting: Taking food or drink into your body.

ppb: Parts per billion.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about 1,2-dibromoethane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to 1,2-dibromoethane can result from drinking groundwater or breathing air that is contaminated. This is most likely to occur in the workplace or from living near a hazardous waste site. 1,2-Dibromoethane can affect the brain, damage skin, damage sperm in males, and even cause death if exposure is very high. This chemical has been found in at least 27 of 1,416 National Priorities List sites identified by the Environmental Protection Agency.

What is 1,2-dibromoethane?

(Pronounced 1,2-dī'brō'mō ēth'ān')

1,2-Dibromoethane is a manufactured chemical. It also occurs naturally in small amounts in the ocean where it is formed, probably by algae and kelp. It is a colorless liquid with a mild, sweet odor. Other names for 1,2-dibromoethane are ethylene dibromide, EDB, and glycol bromide. Trade names include Bromofume and Dowfume.

1,2-Dibromoethane has been used as a pesticide in soil, and on citrus, vegetable, and grain crops. Most of these uses have been stopped by the Environmental Protection Agency (EPA) since 1984. Another major use was as an additive in leaded gasoline; however, since leaded gasoline is now banned, it is no longer used for this purpose. Uses today include treatment of logs for termites and beetles, control of moths in beehives, and as a preparation for dyes and waxes.

What happens to 1,2-dibromoethane when it enters the environment?

- It moves into the environment from manufacturing use and leaks at waste sites.
- When released, it quickly moves to air and will evaporate from surface water and soil to the air.
- It dissolves in water and will move through soil into the groundwater.

- Small amounts remain attached to soil particles.
- It breaks down slowly in air (over 4–5 months), more quickly in surface water (2 months), and hardly at all in groundwater.
- It is not expected to build up in plants or animals.

How might I be exposed to 1,2-dibromoethane?

- Drinking contaminated water, especially well water near farms or waste sites.
- Breathing contaminated workplace air.
- Touching it while bathing or swimming in contaminated water.
- Playing in contaminated soils at waste sites.

How can 1,2-dibromoethane affect my health?

Your exposure to 1,2-dibromoethane is generally much, much lower than levels that can harm you. We don't know the effects on people of breathing high levels, but animal studies with short-term exposures to high levels caused depression and collapse, indicating effects on the brain.

Redness and inflammation, including skin blisters and mouth and stomach ulcers, can occur if large amounts are

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

swallowed. One accidental swallowing caused death in a woman. It is highly unlikely that there would be a risk of death to people from low-level exposure.

Although very little is known about the effects from breathing 1,2-dibromoethane over a long period of time, some male workers had reproductive effects including damage to their sperm. No other long-term effects are known in people.

In rats, death occurred from breathing high levels for a short time. Lower levels caused liver and kidney damage. When rats breathed air or ate food containing 1,2-dibromoethane for short or long periods of time, they were less fertile or had abnormal sperm.

Changes in the brain and behavior were also seen in young rats whose male parents had breathed 1,2-dibromoethane, and birth defects were observed in the young of animals that were exposed while pregnant. 1,2-Dibromoethane is not known to cause birth defects in people.

How likely is 1,2-dibromoethane to cause cancer?

The Department of Health and Human Services has determined that 1,2-dibromoethane may reasonably be anticipated to be a carcinogen.

There are no reports of cancer in workers or other people exposed to 1,2-dibromoethane for several years. However, rats and mice that breathed, swallowed, or touched it for long periods had cancer in many organs.

Is there a medical test to show whether I've been exposed to 1,2-dibromoethane?

There is no reliable medical test to determine whether you have been exposed to 1,2-dibromoethane. Experimental methods exist to measure 1,2-dibromoethane or the bromide

ion, a breakdown product of 1,2-dibromoethane, in blood. These tests cannot be done at your doctor's office, but your doctor may be able to send samples to a special laboratory.

Has the federal government made recommendations to protect human health?

The EPA has set a limit of 0.05 parts of 1,2-dibromoethane per billion parts of drinking water (0.05 ppb). EPA requires that spills into the environment of 1,000 pounds or more of 1,2-dibromoethane be reported.

The Occupational Health and Safety Administration (OSHA) has limited workers' exposure to an average of 20 parts of 1,2-dibromoethane per million parts of air (ppm) for an 8-hour workday over a 40-hour workweek.

The National Institute for Occupational Safety and Health (NIOSH) has limited workers' exposure to 1,2-dibromoethane in air to an average of 0.045 ppm for up to a 10-hour workday over a 40-hour workweek.

Glossary

Carcinogen: A substance that can cause cancer.

Long-term: Lasting one year or longer.

ppb: Parts per billion.

ppm: Parts per million.

Short-term: Lasting 14 days or less.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about 1,2-Dichloroethane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to 1,2-dichloroethane usually occurs by breathing contaminated air in workplaces that use 1,2-dichloroethane. Breathing or ingesting high levels of 1,2-dichloroethane can cause damage to the nervous system, liver, kidneys, and lungs and may cause cancer. This substance has been found in at least 570 of the 1,585 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is 1,2-dichloroethane?

1,2-Dichloroethane, also called ethylene dichloride, is a manufactured chemical that is not found naturally in the environment. It is a clear liquid and has a pleasant smell and sweet taste.

The most common use of 1,2-dichloroethane is in the production of vinyl chloride which is used to make a variety of plastic and vinyl products including polyvinyl chloride (PVC) pipes, furniture and automobile upholstery, wall coverings, housewares, and automobile parts. It is also used to as a solvent and is added to leaded gasoline to remove lead.

What happens to 1,2-dichloroethane when it enters the environment?

- Most of the 1,2-dichloroethane released to the environment is released to the air. In the air, 1,2-dichloroethane breaks down by reacting with other compounds formed by sunlight. It can stay in the air for more than 5 months before it is broken down.
- 1,2-Dichloroethane can also be released into rivers and lakes. It breaks down very slowly in water and most of it will evaporate to the air.

- 1,2-Dichloroethane released in soil will either evaporate into the air or travel down through the soil and enter underground water.

How might I be exposed to 1,2-dichloroethane?

- The general population may be exposed to 1,2-dichloroethane by breathing air or drinking water that contains 1,2-dichloroethane.
- People who work or live near a factory where 1,2-dichloroethane is used, may be exposed to higher than usual levels.
- People living near uncontrolled hazardous waste sites may also be exposed to higher than usual levels of 1,2-dichloroethane.

How can 1,2-dichloroethane affect my health?

Nervous system disorders, liver and kidney diseases, and lung effects have been reported in humans ingesting or inhaling large amounts of 1,2-dichloroethane.

In laboratory animals, breathing or ingesting large amounts of 1,2-dichloroethane have also caused nervous system disorders and liver, kidney, and lung effects. Animal studies also suggest that 1,2-dichloroethane may damage the

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

immune system. Kidney disease has also been seen in animals ingesting low doses of 1,2-dichloroethane for a long time. Studies in animals indicate that 1,2-dichloroethane does not affect reproduction.

How likely is 1,2-dichloroethane to cause cancer?

Human studies examining whether 1,2-dichloroethane can cause cancer have been considered inadequate. In animals, increases in the occurrence of stomach, mammary gland, liver, lung, and endometrium cancers have been seen following inhalation, oral, and dermal exposure.

The Department of Health and Human Services (DHHS) has determined that 1,2-dichloroethane may reasonably be expected to cause cancer. The EPA has determined that 1,2-dichloroethane is a probable human carcinogen and the International Agency for Cancer Research (IARC) considers it to be a possible human carcinogen.

How can 1,2-dichloroethane affect children?

We do not know if exposure to 1,2-dichloroethane will result in birth defects or other developmental effects in people. Studies in animals suggest that 1,2-dichloroethane does not produce birth defects.

It is likely that health effects seen in children exposed to high levels of 1,2-dichloroethane will be similar to the effects seen in adults.

How can families reduce the risk of exposure to 1,2-dichloroethane?

The general population is not likely to be exposed to large amounts of 1,2-dichloroethane. In the past, it was used in small amounts in household products such as cleaning agents, pesticides, and wallpaper and carpet glue. Risk of

exposure from this source could be eliminated if these older products were immediately discarded.

Children should avoid playing in soils near uncontrolled hazardous waste sites where 1,2-dichloroethane may have been discarded.

Is there a medical test to show whether I've been exposed to 1,2-dichloroethane?

Tests are available to measure 1,2-dichloroethane in breath, blood, breast milk, and urine of exposed people. Because 1,2-dichloroethane leaves the body fairly quickly, these tests need to be done within a couple of days of exposure. These tests cannot be used to predict the nature or severity of toxic effects. These tests are not usually done in the doctor's office.

Has the federal government made recommendations to protect human health?

The EPA allows 0.005 milligrams of 1,2-dichloroethane per liter of drinking water (0.005 mg/L).

The Occupational Safety and Health Administration has set a limit of 50 parts of 1,2-dichloroethane per million parts of air (50 ppm) in workplace air for 8 hour shifts and 40 hour work weeks.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about 1,2-dichloropropane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: 1,2-Dichloropropane is primarily used to make other chlorinated chemicals. Exposure to high levels of 1,2-dichloropropane can damage the liver, kidneys, blood, and lungs, and affect the brain. It has been found at 26 of the 1,177 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is 1,2-dichloropropane?

(Pronounced 1,2-dī-klôr'ō-prō/pān)

1,2-Dichloropropane is a colorless, flammable liquid with a chloroform-like odor. It is moderately soluble in water and readily evaporates into air. It does not occur naturally in the environment.

1,2-Dichloropropane production in the United States has declined over the past 20 years. It was used in the past as a soil fumigant, chemical intermediate, and industrial solvent and was found in paint strippers, varnishes, and furniture finish removers. Most of these uses were discontinued. Today, almost all of the 1,2-dichloropropane is used as a chemical intermediate to make perchloroethylene and several other related chlorinated chemicals.

What happens to 1,2-dichloropropane when it enters the environment?

- 1,2-Dichloropropane released to air can spread to areas far from where it was released because it is not rapidly broken down by reactions with other chemicals and sunlight.
- Most of the 1,2-dichloropropane in water will evaporate to the air.

- When released to soil, it is not easily broken down by bacteria, but will easily evaporate to the air and filter into the groundwater.
- 1,2-Dichloropropane does not build up in the food chain.

How might I be exposed to 1,2-dichloropropane?

- Most people are not likely to be exposed to 1,2-dichloropropane because of its limited use.
- If you work where 1,2-dichloropropane is made or used, you could be exposed by breathing air that contains its vapors or by spilling or splashing it on your skin.
- People who live near a waste site containing 1,2-dichloropropane could be exposed by drinking contaminated groundwater, breathing vapors released to the air, or getting contaminated soil on their skin.

How can 1,2-dichloropropane affect my health?

People who intentionally or accidentally breathe high levels of 1,2-dichloropropane have experienced difficulty breathing, coughing, vomiting, nosebleed, fatigue, and damage to blood cells, liver, and kidneys. People who accidentally drank cleaning solutions containing 1,2-dichloropropane experienced headaches, dizziness, nausea, liver and kidney damage, anemia, coma, and death.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

Animal studies indicate that breathing low levels of 1,2-dichloropropane over short- or long-term periods causes damage to the liver, kidney, and respiratory system. Breathing high levels causes death. Similar effects have been reported when animals were given 1,2-dichloropropane by mouth. Some studies indicate that ingesting 1,2-dichloropropane may cause reproductive effects. One study reported a delay in bone formation of the skull in fetal rats following exposure of the mother rats to 1,2-dichloropropane.

How likely is 1,2-dichloropropane to cause cancer?

It is not known whether 1,2-dichloropropane causes cancer in people. The carcinogenicity of 1,2-dichloropropane has been evaluated in animal studies with rats and mice. Liver tumors have been observed in mice, and mammary gland tumors have been found in rats. The International Agency for Research on Cancer (IARC) has determined that 1,2-dichloropropane is unclassifiable as to human carcinogenicity.

Is there a medical test to show whether I've been exposed to 1,2-dichloropropane?

Urine and blood tests can be used to find out if you have been exposed to 1,2-dichloropropane. Levels measured in the urine can be used to predict the levels in the air. These tests cannot predict whether you will suffer harmful effects. Because special equipment is needed, these tests are not usually done in the doctor's office.

Has the federal government made recommendations to protect human health?

The EPA has set a Maximum Contaminant Level (MCL) of 0.005 parts per million (0.005 ppm) for 1,2-dichloropropane in drinking water. The EPA recommends that the level of 1,2-

dichloropropane in lakes and streams should be limited to 0.52 parts per billion (0.52 ppb) to prevent possible human health effects from drinking contaminated water or eating contaminated fish. Any release to the environment greater than 1,000 pounds of 1,2-dichloropropane must be reported to the EPA.

The Occupational Safety and Health Administration (OSHA) has set a workplace air concentration limit of 75 ppm over an 8-hour workday, 40-hour workweek.

The federal recommendations have been updated as of July 1999.

Glossary

Anemia: A decreased ability of the blood to transport oxygen.

Carcinogenicity: Ability to cause cancer.

CAS: Chemical Abstracts Service.

Evaporate: To change into a vapor or a gas.

Long-term: Lasting one year or longer.

National Priorities List: A list of the nation's worst hazardous waste sites.

ppb: Parts per billion.

ppm: Parts per million.

Short-term: Lasting 14 days or less.

Tumor: An abnormal mass of tissue.

This fact sheet answers the most frequently asked health questions (FAQs) about 1,3-butadiene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to 1,3-butadiene occurs mainly from breathing contaminated air. Effects on the nervous system and irritations of the eyes, nose, and throat have been seen in people who breathed contaminated air. This chemical has been found in at least 7 of 1,416 National Priorities List sites identified by the Environmental Protection Agency.

What is 1,3-butadiene?

(Pronounced 1,3-byōō'tə-dī'ēn')

1,3-Butadiene is a chemical made from the processing of petroleum. It is the 36th highest volume chemical produced in the United States. It is a colorless gas with a mild gasoline-like odor.

About 75% of the manufactured 1,3-butadiene is used to make synthetic rubber. Synthetic rubber is widely used for tires on cars and trucks.

1,3-Butadiene is also used to make plastics including acrylics. Small amounts are found in gasoline.

What happens to 1,3-butadiene when it enters the environment?

- It quickly evaporates to the air as a gas from leaks during production, use, storage, transport, or disposal.
- It breaks down quickly in air by sunlight; in sunny weather, half of it breaks down in about 2 hours.
- When not sunny, it takes a few days for about half of it to break down in the air.
- It evaporates very quickly from water and soil.
- Since it evaporates so easily, it is not expected to be found in water or soil, but adequate tests are not available to measure the amounts.

- 1,3-Butadiene may be broken down by microorganisms in the soil.
- It is not expected to accumulate in fish.

How might I be exposed to 1,3-butadiene?

- Breathing urban and suburban air, but these levels are generally very low except in polluted cities or near chemical, plastic, and rubber facilities that use it.
- Breathing contaminated workplace air where it is manufactured or used.
- Breathing contaminated air from car and truck exhaust, waste incineration, or wood fires.
- Breathing cigarette smoke.
- Drinking contaminated water near production or waste sites.
- Ingesting foods contained in plastic or rubber food containers, but levels are generally very low or not present at all.
- Skin contact with gasoline, but levels are low.

How can 1,3-butadiene affect my health?

Most of the information on the health effects of 1,3-butadiene comes from studies where the exposure was from breathing contaminated air.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

Breathing very high levels of 1,3-butadiene for a short time can cause central nervous system damage, blurred vision, nausea, fatigue, headache, decreased blood pressure and pulse rate, and unconsciousness. There are no recorded cases of accidental exposures at high levels that caused death in humans, but this could occur.

Breathing lower levels may cause irritation of the eyes, nose, and throat.

Studies on workers who had longer exposures with lower levels have shown an increase in heart and lung damage, but these workers were also exposed to other chemicals. We don't know for sure which chemical (or chemicals) caused the effects. We also do not know what levels in the air will cause these effects in people when breathed over many years.

Animal studies show that breathing 1,3-butadiene during pregnancy can increase the number of birth defects. Other effects seen in animals that breathed low levels of 1,3-butadiene for one year include kidney and liver disease, and damaged lungs. Some of the animals died.

There is no information on the effects of eating or drinking 1,3-butadiene. Skin contact with liquid 1,3-butadiene can cause irritation and frostbite.

How likely is 1,3-butadiene to cause cancer?

The Department of Health and Human Services has determined that 1,3-butadiene may reasonably be anticipated to be a carcinogen. This is based on animal studies that found increases in a variety of tumor types from exposure to 1,3-butadiene.

Studies on workers are inconclusive because the workers were exposed to other chemicals in addition to 1,3-butadiene.

Is there a medical test to show whether I've been exposed to 1,3-butadiene?

There is currently no reliable medical test to determine whether you have been exposed to 1,3-butadiene. However, scientists are working on methods to measure it in the blood.

Has the federal government made recommendations to protect human health?

The Environmental Protection Agency (EPA) requires that discharges or spills into the environment of 1 pound or more of 1,3-butadiene be reported.

The Occupational Safety and Health Administration (OSHA) has set an occupational exposure limit of 1,000 parts of 1,3-butadiene per million parts of air (1,000 ppm).

The National Institute for Occupational Safety and Health (NIOSH) recommends that 1,3-butadiene be kept to the lowest feasible concentration because of its potential to cause cancer.

Glossary

Carcinogen: A substance that can cause cancer.

Ingesting: Taking food or drink into your body.

ppm: Parts per million.

Tumor: An abnormal mass of tissue.

This fact sheet answers the most frequently asked health questions (FAQs) about dichlorobenzenes. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because these substances may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to dichlorobenzenes mostly occurs from breathing indoor air or workplace air. Exposure to high levels of 1,2- or 1,4-dichlorobenzene may be very irritating to your eyes and nose and cause difficult breathing, and an upset stomach. Extremely high exposures to 1,4-dichlorobenzene can result in dizziness, headaches, and liver problems. 1,2-, 1,3-, and 1,4-Dichlorobenzenes have been identified in at least 281, 175, and 330, respectively, of the 1,662 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What are dichlorobenzenes?

There are three dichlorobenzene isomers- 1,2-dichlorobenzene, 1,3-dichlorobenzene, and 1,4-dichlorobenzene. Dichlorobenzenes do not occur naturally. 1,2-Dichlorobenzene is a colorless to pale yellow liquid used to make herbicides. 1,3-Dichlorobenzene is a colorless liquid used to make herbicides, insecticides, medicine, and dyes. 1,4-Dichlorobenzene, the most important of the three chemicals, is a colorless to white solid with a strong, pungent odor. When exposed to air, it slowly changes from a solid to a vapor. Most people can smell 1,4-dichlorobenzene in the air at very low levels.

What happens to dichlorobenzenes when they enter the environment?

- 1,4-Dichlorobenzene enters the environment when it is used in mothballs and in toilet-deodorizer blocks. Very little enters the environment from hazardous waste sites.
- Some 1,2- and 1,3-dichlorobenzenes are released into the environment when used to make herbicides and when people use products that contain these chemicals.
- Dichlorobenzenes do not dissolve easily in water, the small amounts that enter water quickly evaporate into the air.
- Sometimes, dichlorobenzenes bind to soil and sediment. Dichlorobenzenes in soil usually are not easily broken down by

soil organisms. Evidence suggests that plants and fish absorb dichlorobenzenes.

How might I be exposed to dichlorobenzenes?

- You may be exposed to 1,4-dichlorobenzene by breathing vapors from products used in the home or in buildings, such as air fresheners, mothballs, and toilet-deodorizer blocks. 1,2-dichlorobenzene and 1,3-dichlorobenzene are not found frequently in the air of homes and buildings because these chemicals are not used in household products.
- You may be exposed to very low levels of dichlorobenzenes in drinking water. You are not likely to be exposed to dichlorobenzenes in soil.
- You may also be exposed to low levels of dichlorobenzenes in beef, pork, chicken, eggs, baked goods, soft drinks, butter, peanut butter, fruits, vegetables, and fish.

How can dichlorobenzenes affect my health?

Very little is known about the health effects of 1,3-dichlorobenzene, especially in humans, but they are likely to be similar to those of 1,2- and 1,4-dichlorobenzene.

Inhaling the vapor or dusts of 1,2-dichlorobenzene and 1,4-dichlorobenzene at very high concentrations could be very irritating to your eyes and nose and cause burning and tearing

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

of the eyes, coughing, difficult breathing, and an upset stomach. Dizziness, headaches, and liver problems have also been observed in people exposed to very high levels of 1,4-dichlorobenzene. There is limited evidence that inhaling 1,4-dichlorobenzene may decrease lung function.

People who have eaten 1,4-dichlorobenzene products regularly for long periods (months to years) developed skin blotches and anemia. 1,4-Dichlorobenzene might cause a burning feeling in your skin if you hold mothballs or toilet-deodorizer blocks against your skin for a long time.

Breathing or eating any of the dichlorobenzenes caused harmful effects in the liver of laboratory animals. Animal studies also found that 1,2- and 1,4-dichlorobenzene caused effects in the kidneys and blood, and that 1,3-dichlorobenzene caused thyroid and pituitary effects.

How likely are dichlorobenzenes to cause cancer?

The Department of Health and Human Services (DHHS) has determined that 1,4-dichlorobenzene may reasonably be anticipated to be a carcinogen. There is no direct evidence that 1,4-dichlorobenzene can cause cancer in humans. However, animals given very high levels in water developed liver tumors. 1,2-Dichlorobenzene was not carcinogenic in laboratory animals and 1,3-dichlorobenzene has not been tested for its potential to cause cancer. Both the International Agency for Research on Cancer (IARC) and the EPA concluded that 1,2- and 1,3-dichlorobenzene are not classifiable as to human carcinogenicity.

How can dichlorobenzenes affect children?

Children who are exposed to dichlorobenzenes are likely to exhibit the same effects as adults, although this is not known for certain. Children can also be exposed to dichlorobenzenes prenatally, because all three isomers have been detected in placenta samples, as well as through breast feeding. There is no reliable evidence suggesting that dichlorobenzenes cause birth defects, although animal data raise concern for effects of 1,4-dichlorobenzene on postnatal development of the nervous system.

How can families reduce the risk of exposure to dichlorobenzenes?

Exposure of children to 1,4-dichlorobenzene can be minimized by discouraging them from playing with, swallowing, or having skin contact with products containing 1,4-dichlorobenzene. These items should be stored out of reach of young children and kept in their original containers to prevent accidental poisonings. Keep your Poison Control Center's number by the phone.

Is there a medical test to show whether I've been exposed to dichlorobenzenes?

Several tests can be used to show if you have been exposed to dichlorobenzenes. The most commonly used tests measure their dichlorophenol breakdown products in urine and blood. The presence of the dichlorophenol breakdown products in the urine indicates a person has been exposed to dichlorobenzenes within the previous day or two. Another test measures the levels of dichlorobenzenes in your blood, but this is used less often. These tests require special equipment that is not routinely available in a doctor's office, but they can be performed in a special laboratory. Neither of these tests can be used to show how high the level of dichlorobenzene exposure was or to predict whether harmful health effects will follow.

Has the federal government made recommendations to protect human health?

EPA regulates the levels of dichlorobenzenes that are allowable in drinking water. The highest level of 1,4-dichlorobenzene allowed in drinking water is 0.075 parts 1,4-dichlorobenzene per 1 million parts of water (0.075 ppm).

The Occupational Safety and Health Administration (OSHA) has set a limit for 1,4-dichlorobenzene of 75 parts 1,4-dichlorobenzene per 1 million parts of air (75 ppm) in the workplace.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology and Environmental Medicine, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet was created from information presented in the National Library of Medicine Hazardous Substances Data Bank. This fact sheet answers the most frequently asked health questions (FAQs) about 4-chloroaniline. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: 4-chloroaniline is a chemical that is used to make a number of products, including agricultural chemicals, dyes and pigments, cosmetics, and pharmaceutical products. It is rapidly absorbed by all routes of exposure (inhalation, dermal contact, etc.) and induces methemoglobinemia, a disorder that reduces the ability of the blood to transport oxygen throughout the body. Symptoms of methemoglobinemia include bluish skin, headache, dizziness, weakness, lethargy, loss of coordination, shortness of breath, coma, and death. 4-chloroaniline is believed to cause cancer in animals and is possibly carcinogenic to humans.

What is 4-chloroaniline?

4-chloroaniline is a white or pale yellow solid that has a slightly sweetish odor. It is used as an intermediate in the production of a number of products, including agricultural chemicals, dyes and pigments, cosmetics, and pharmaceutical products.

What happens to 4-chloroaniline when it enters the environment?

- 4-Chloroaniline's production and use in the manufacture of products may result in its release to the environment through waste streams.
- It is also a widespread soil contaminant resulting from the use of phenylurea herbicide which degrades into 4-chloroaniline.
- If released to air, 4-chloroaniline will exist solely as a vapor in the atmosphere.
- If released to soil, 4-chloroaniline is expected to not be able to pass through soil well (low mobility) depending on soil properties.
- Volatilization from moist soil surfaces is expected but is not expected to volatilize from dry soil surfaces.

How might I be exposed to 4-chloroaniline?

- You may be exposed to 4-chloroaniline if you live near a hazardous waste site that contains it or near an industrial building where the chemical is used.
- Monitoring data indicate that the general population may be exposed to 4-chloroaniline via ingestion of food and drinking water.
- 4-Chloroaniline present in chlorhexidine, which is used in disinfection of soft contact lenses;

therefore wearers of soft contact lenses may be exposed to 4-chloroaniline.

- Occupational exposure to 4-chloroaniline may occur through inhalation and dermal contact with this compound at workplaces where 4-chloroaniline is produced or used.

How can 4-chloroaniline affect my health?

- Aniline is a skin and eye irritant and a mild dermal sensitizer.
- It is rapidly absorbed by all routes of exposure (inhalation, dermal contact, etc.) and induces methemoglobinemia, a disorder that reduces the ability of the blood to transport oxygen throughout the body. Symptoms of methemoglobinemia include bluish skin, headache, dizziness, weakness, lethargy, loss of coordination, shortness of breath, coma, and death.
- Data on occupational exposure of humans to 4-chloroaniline are mostly from a few older reports of severe intoxications after accidental exposure during production. Symptoms include increased methemoglobin and sulfhemoglobin levels, bluish skin, the development of anemia, and changes due to anoxia, a condition where bodily tissues are deprived of oxygen to such a degree that permanent damage results.

How likely is 4-chloroaniline to cause cancer?

- There is sufficient evidence in experimental animals for the carcinogenicity of 4-chloroaniline.
- The International Agency for Research on Cancer (IARC) has determined that 4-chloroaniline is possibly carcinogenic to humans while the United States Environmental Protection Agency (USEPA) has not evaluated this substance to determine if it is a possible human carcinogen.

How can 4-chloroaniline affect children?

Exposure of children to large amounts of 4-chloroaniline is assumed to have the same effects as those observed in adults (i.e. methemoglobinemia resulting in bluish skin, headache, dizziness, weakness, lethargy, loss of coordination, shortness of breath, coma, and death).

How can families reduce the risks of exposure to 4-chloroaniline?

Exposure to high amounts of 4-chloroaniline is unlikely because the chemical is not used in household products.

Is there a medical test to determine whether I've been exposed to 4-chloroaniline?

There are medical tests that evaluate urine to determine whether you have been exposed to 4-chloroaniline.

Has the federal government made recommendations to protect human health?

- The USEPA has not established a maximum contaminant level (MCL) for 4-chloroaniline.
- The Occupational Safety and Health Administration (OSHA) has not established a permissible exposure limit for 4-chloroaniline.

Where Can I Get More Information? More information on the adverse effects 4-chloroaniline can be obtained from your community or state health or environmental quality department.

This fact sheet was created from information presented in the United States Environmental Protection Agency (USEPA) Health Assessment Document for Acetaldehyde (USEPA, 1987). This fact sheet answers the most frequently asked health questions (FAQs) about acetaldehyde. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: Acetaldehyde is prevalent in the environment as a natural product of plant respiration and from human activities such as wood burning, burning of tobacco, coffee roasting, and coal refining and waste processing. Acetaldehyde can also enter the environment during accidental spills during its manufacture and use. Acetaldehyde can cause irritation of the skin, eyes, nose, and throat. High levels of exposure can cause fluid accumulation in the lungs and may cause some forms of cancer.

What is acetaldehyde?

Acetaldehyde, also known as acetic aldehyde, ethanal, ethyl aldehyde, and methyl formaldehyde is a colorless liquid that is highly reactive and oxidizes in air. Acetaldehyde has a pungent odor, but at diluted concentrations the odor is fruity and pleasant. It is mainly used as an intermediate in the synthesis of other chemicals, but other uses include production of perfumes, polyester resins, dyes, and as a food preservative and flavoring agent.

Acetaldehyde is prevalent in the environment as a natural product of plant respiration and from human activities such as wood burning, burning of tobacco, coffee roasting, coal refining, and waste processing.

What happens to acetaldehyde when it enters the environment?

- Acetaldehyde dissolves easily in water and can easily leach into soil.
- In soil, sewage, and natural water systems acetaldehyde is readily degraded and metabolized by microorganisms.
- Acetaldehyde does not build up in plants or animals because it is readily metabolized.

How might I be exposed to acetaldehyde?

- Breathing ambient air.
- Exposure may occur in individuals occupationally exposed to acetaldehyde during its manufacture and use.
- Ingesting food which uses acetaldehyde as a preservative or additive.

- Cigarettes and other tobacco products, and wood fire places are sources of acetaldehyde exposure.
- Acetaldehyde is formed in the body from the breakdown of ethanol, which occurs after the consumption of alcoholic beverages.

How can acetaldehyde affect my health?

- Inhaling low levels of acetaldehyde can cause irritation of the eyes, skin, and respiratory tract.
- At higher exposure levels redness of the skin (erythema), fluid accumulation in the lungs (pulmonary edema), and premature cell death (necrosis) may also occur.
- Symptoms of long term, high level exposure to acetaldehyde resemble those of alcoholism.

How likely is acetaldehyde to cause cancer?

Acetaldehyde is considered a probable human carcinogen by the USEPA (United States Environmental Protection Agency). This means that acetaldehyde has been shown to produce cancer in laboratory animals, and that it may therefore be able to produce cancer in humans.

How can acetaldehyde affect children?

- The most common route of exposure is by breathing acetaldehyde, which is likely to cause nose and eye irritation (burning, itchy, tearing, and sore throat) in children as well as in adults.
- There is not sufficient data to evaluate the reproductive or developmental effects of acetaldehyde in humans. In animals, it has been shown to cross the placenta to the fetus.

How can families reduce the risks of exposure to acetaldehyde?

Acetaldehyde is usually found in the air, and levels are usually higher indoors than outdoors. Opening windows and using fans to bring fresh air indoors are the easiest ways to lower levels in the house. Not smoking and not using unvented heaters indoors can lower the acetaldehyde levels.

Is there a medical test to determine whether I've been exposed to acetaldehyde?

Acetaldehyde can be measured in the blood and breath to determine whether or not exposure has occurred.

Has the federal government made recommendations to protect human health?

- The Occupational Safety and Health Administration (OSHA) has set a permissible exposure limit for acetaldehyde of 360 mg/m³ for an 8-hour workday, 40-hour workweek.
- According to the Joint Expert Committee on Food Additives (JECFA) of the Food and Agriculture Organization of the United Nations/World Health Organization and the European Commission's Scientific Committee on Food, acetaldehyde does not have a set acceptable daily intake (ADI) because there are no safety concerns at current levels of intake when used as a flavoring agent.

References

United States Environmental Protection Agency (USEPA). 1987. Health Assessment Document for Acetaldehyde. EPA/600/8-86-015A. Environmental Criteria and Assessment Office, Office of Health and Environmental Assessment, Office of Research and Development, Research Triangle Park, NC.

Where Can I Get More Information? More information on the adverse effects of acetaldehyde can be obtained from your community or state health or environmental quality department.

This fact sheet answers the most frequently asked health questions (FAQs) about acrolein. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to acrolein occurs mostly from breathing it in air. Cigarette smoke and automobile exhaust contain acrolein. Acrolein causes burning of the nose and throat and can damage the lungs. Acrolein has been found in at least 31 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is acrolein?

Acrolein is a colorless or yellow liquid with a disagreeable odor. It dissolves in water very easily and quickly changes to a vapor when heated. It also burns easily. Small amounts of acrolein can be formed and can enter the air when trees, tobacco, other plants, gasoline, and oil are burned.

Acrolein is used as a pesticide to control algae, weeds, bacteria, and mollusks. It is also used to make other chemicals.

What happens to acrolein when it enters the environment?

- Acrolein may be found in soil, water, or air.
- It breaks down fairly rapidly in the air (about half will disappear within 1 day) by reacting with other chemicals and sunlight.
- Acrolein evaporates rapidly from soil and water.

How might I be exposed to acrolein?

- Smoking tobacco or breathing air containing tobacco smoke or automobile exhaust.
- Working in or living near industries where acrolein is manufactured or used to make other chemicals.
- Inhaling vapors from overheated cooking oil or grease.

How can acrolein affect my health?

There is very little information about how exposure to acrolein affects people's health. The information we have indicates that breathing large amounts damages the lungs and could cause death. Breathing lower amounts may cause eye watering and burning of the nose and throat and a decreased breathing rate.

Animal studies show that breathing acrolein causes irritation to the nasal cavity, lowered breathing rate, and damage to the lining of the lungs.

We do not know if eating food or drinking water containing acrolein affects your health. However, animals that swallowed acrolein had stomach irritation, vomiting, stomach ulcers, and bleeding.

How likely is acrolein to cause cancer?

The Department of Health and Human Services (DHHS) has not classified acrolein as to its carcinogenicity. The International Agency for Research on Cancer (IARC) has determined that acrolein is not classifiable as to carcinogenicity in humans. The EPA has stated that the potential carcinogenicity of acrolein cannot be determined based on an inadequate database.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

How can acrolein affect children?

In general, children are not likely to be affected by acrolein more than adults. However, children who are sensitive to irritants in the air (such as children with asthma) may be more sensitive to lung irritation from acrolein.

In animal studies, ingestion of very large amounts of acrolein during pregnancy caused reduced birth weights and skeletal deformities in newborns. However, the levels causing these effects were often fatal to the mother.

How can families reduce the risks of exposure to acrolein?

You can reduce your family's exposure to acrolein by reducing their exposure to tobacco smoke, smoke from burning wood products or cooking oils and grease, and exhaust from diesel or gasoline vehicles.

Is there a medical test to determine whether I've been exposed to acrolein?

Methods have been developed to detect acrolein or breakdown products of acrolein in biological or environmental samples; however, there are no specific medical tests available in a doctor's office to determine if you have been exposed to acrolein.

Has the federal government made recommendations to protect human health?

The Food and Drug Administration (FDA) has determined that the amount of acrolein used to prepare modified food starch must not be more than 0.6%.

The Occupational Safety and Health Administration (OSHA) has set limits of 0.1 parts of acrolein per million parts of workplace air (0.01 ppm) for 8 hour shifts and 40 hour work weeks.

The EPA has restricted the use of all pesticides containing acrolein.

This fact sheet answers the most frequently asked health questions (FAQs) about acrylonitrile. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to acrylonitrile occurs mostly from breathing it in the air. Acrylonitrile primarily affects the nervous system and lungs. If it is spilled on the skin, the skin will turn red and blisters may form. This chemical has been found in at least 3 of the 1,177 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is acrylonitrile?

(Pronounced ə-krīl/ō nī-trīl)

Acrylonitrile is a colorless, liquid, man-made chemical with a sharp, onion- or garlic-like odor. It can be dissolved in water and evaporates quickly.

Acrylonitrile is used to make other chemicals such as plastics, synthetic rubber, and acrylic fibers. A mixture of acrylonitrile and carbon tetrachloride was used as a pesticide in the past; however, all pesticide uses have stopped.

What happens to acrylonitrile when it enters the environment?

- Acrylonitrile may be found in the soil, water, or air near industrial sites where it is made, or at hazardous waste sites where it has been disposed of.
- Because acrylonitrile evaporates easily, most of it is released to the air from facilities where it is produced and used.
- In air, acrylonitrile breaks down quickly (about half will disappear within 5 to 50 hours) by reacting with other chemicals and sunlight.
- Acrylonitrile can enter groundwater by filtering through the soil, but it is not commonly found in groundwater.

- It is broken down by bacteria in surface water.
- When it is released to soil, some of it will be broken down by bacteria, but most of it will evaporate to the air or filter to groundwater.
- Acrylonitrile does not build up in the food chain.

How might I be exposed to acrylonitrile?

- Unless you live near a factory where acrylonitrile is made or near a hazardous waste site that contains acrylonitrile, you are unlikely to be exposed to it.
- Breathing contaminated air near hazardous waste sites that contain acrylonitrile.
- Working in, or living near, industries where it is manufactured or used.
- Swallowing food and water that contains small amounts of acrylonitrile.

How can acrylonitrile affect my health?

Breathing high concentrations of acrylonitrile will cause nose and throat irritation, tightness in the chest, difficulty breathing, nausea, dizziness, weakness, headache, impaired judgment, and convulsions. These symptoms usually disappear when exposure is stopped. If spilled on the skin, acrylonitrile will burn the skin and produce redness and blisters.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

Animal studies show effects from breathing acrylonitrile. These effects include irritation to the nasal cavity and lungs, changes in the breathing rate, fluid accumulation in the lungs, weakness, and paralysis. Decreased fertility and birth defects have been observed in some laboratory animals exposed to high concentrations of acrylonitrile in air or drinking water.

There is evidence that children are much more sensitive to acrylonitrile than adults. In a few cases, children have died following exposure to acrylonitrile vapors that caused only minor nose and throat irritation in adults.

How likely is acrylonitrile to cause cancer?

The Department of Health and Human Services (DHHS) has determined that acrylonitrile may reasonably be anticipated to cause cancer in people. Studies of people are inconclusive, while animal studies have shown cancers of the brain and mammary glands.

Is there a medical test to show whether I've been exposed to acrylonitrile?

There is a test that can detect acrylonitrile in blood. Other tests can be used to measure the breakdown products (metabolites) of acrylonitrile in urine. One of the metabolites (cyanide) could come from other chemicals you might have been exposed to, so it is not a definite indicator of acrylonitrile exposure. The results of these tests could also be affected by cigarette smoking. Special equipment is needed for these tests, and they are not routinely available in a doctor's office.

Has the federal government made recommendations to protect human health?

The EPA recommends that levels in lakes and streams should be limited to 0.058 parts of acrylonitrile per billion parts of water (0.058 ppb) to prevent possible health effects

from drinking water or eating fish contaminated with acrylonitrile. Any release to the environment greater than 100 pounds of acrylonitrile must be reported to the EPA.

The Occupational Safety and Health Administration (OSHA) has set a limit of 2 ppm over an 8-hour workday, 40-hour workweek.

The National Institute of Occupational Safety and Health (NIOSH) recommends that average workplace air should not exceed 1 part per million (1 ppm) acrylonitrile averaged over a 10-hour period.

The federal recommendations have been updated as of July 1999.

Glossary

CAS: Chemical Abstracts Service.

Evaporate: To change into a vapor or a gas.

National Priorities List: A list of the nation's worst hazardous waste sites.

Pesticide: A substance that kills pests.

ppb: Parts per billion.

ppm: Parts per million.

This fact sheet answers the most frequently asked health questions (FAQs) about arsenic. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to higher than average levels of arsenic occur mostly in the workplace, near hazardous waste sites, or in areas with high natural levels. At high levels, inorganic arsenic can cause death. Exposure to lower levels for a long time can cause a discoloration of the skin and the appearance of small corns or warts. Arsenic has been found in at least 1,149 of the 1,684 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is arsenic?

Arsenic is a naturally occurring element widely distributed in the earth's crust. In the environment, arsenic is combined with oxygen, chlorine, and sulfur to form inorganic arsenic compounds. Arsenic in animals and plants combines with carbon and hydrogen to form organic arsenic compounds.

Inorganic arsenic compounds are mainly used to preserve wood. Copper chromated arsenate (CCA) is used to make "pressure-treated" lumber. CCA is no longer used in the U.S. for residential uses; it is still used in industrial applications. Organic arsenic compounds are used as pesticides, primarily on cotton fields and orchards.

What happens to arsenic when it enters the environment?

- Arsenic occurs naturally in soil and minerals and may enter the air, water, and land from wind-blown dust and may get into water from runoff and leaching.
- Arsenic cannot be destroyed in the environment. It can only change its form.
- Rain and snow remove arsenic dust particles from the air.
- Many common arsenic compounds can dissolve in water. Most of the arsenic in water will ultimately end up in soil or sediment.
- Fish and shellfish can accumulate arsenic; most of this arsenic is in an organic form called arsenobetaine that is much less harmful.

How might I be exposed to arsenic?

- Ingesting small amounts present in your food and water or breathing air containing arsenic.
- Breathing sawdust or burning smoke from wood treated with arsenic.
- Living in areas with unusually high natural levels of arsenic in rock.
- Working in a job that involves arsenic production or use, such as copper or lead smelting, wood treating, or pesticide application.

How can arsenic affect my health?

Breathing high levels of inorganic arsenic can give you a sore throat or irritated lungs.

Ingesting very high levels of arsenic can result in death. Exposure to lower levels can cause nausea and vomiting, decreased production of red and white blood cells, abnormal heart rhythm, damage to blood vessels, and a sensation of "pins and needles" in hands and feet.

Ingesting or breathing low levels of inorganic arsenic for a long time can cause a darkening of the skin and the appearance of small "corns" or "warts" on the palms, soles, and torso.

Skin contact with inorganic arsenic may cause redness and swelling.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Almost nothing is known regarding health effects of organic arsenic compounds in humans. Studies in animals show that some simple organic arsenic compounds are less toxic than inorganic forms. Ingestion of methyl and dimethyl compounds can cause diarrhea and damage to the kidneys

How likely is arsenic to cause cancer?

Several studies have shown that ingestion of inorganic arsenic can increase the risk of skin cancer and cancer in the liver, bladder, and lungs. Inhalation of inorganic arsenic can cause increased risk of lung cancer. The Department of Health and Human Services (DHHS) and the EPA have determined that inorganic arsenic is a known human carcinogen. The International Agency for Research on Cancer (IARC) has determined that inorganic arsenic is carcinogenic to humans.

How can arsenic affect children?

There is some evidence that long-term exposure to arsenic in children may result in lower IQ scores. There is also some evidence that exposure to arsenic in the womb and early childhood may increase mortality in young adults.

There is some evidence that inhaled or ingested arsenic can injure pregnant women or their unborn babies, although the studies are not definitive. Studies in animals show that large doses of arsenic that cause illness in pregnant females, can also cause low birth weight, fetal malformations, and even fetal death. Arsenic can cross the placenta and has been found in fetal tissues. Arsenic is found at low levels in breast milk.

How can families reduce the risks of exposure to arsenic?

If you use arsenic-treated wood in home projects, you should wear dust masks, gloves, and protective clothing to decrease exposure to sawdust.

- If you live in an area with high levels of arsenic in water or soil, you should use cleaner sources of water and limit contact with soil.
- If you work in a job that may expose you to arsenic, be aware that you may carry arsenic home on your clothing, skin, hair, or tools. Be sure to shower and change clothes before going home.

Is there a medical test to determine whether I've been exposed to arsenic?

There are tests available to measure arsenic in your blood, urine, hair, and fingernails. The urine test is the most reliable test for arsenic exposure within the last few days. Tests on hair and fingernails can measure exposure to high levels of arsenic over the past 6-12 months. These tests can determine if you have been exposed to above-average levels of arsenic. They cannot predict whether the arsenic levels in your body will affect your health.

Has the federal government made recommendations to protect human health?

The EPA has set limits on the amount of arsenic that industrial sources can release to the environment and has restricted or cancelled many of the uses of arsenic in pesticides. EPA has set a limit of 0.01 parts per million (ppm) for arsenic in drinking water.

The Occupational Safety and Health Administration (OSHA) has set a permissible exposure limit (PEL) of 10 micrograms of arsenic per cubic meter of workplace air ($10 \mu\text{g}/\text{m}^3$) for 8 hour shifts and 40 hour work weeks.

This fact sheet answers the most frequently asked health questions (FAQs) about benzene. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Benzene is a widely used chemical formed from both natural processes and human activities. Breathing benzene can cause drowsiness, dizziness, and unconsciousness; long-term benzene exposure causes effects on the bone marrow and can cause anemia and leukemia. Benzene has been found in at least 1,000 of the 1,684 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is benzene?

Benzene is a colorless liquid with a sweet odor. It evaporates into the air very quickly and dissolves slightly in water. It is highly flammable and is formed from both natural processes and human activities.

Benzene is widely used in the United States; it ranks in the top 20 chemicals for production volume. Some industries use benzene to make other chemicals which are used to make plastics, resins, and nylon and other synthetic fibers. Benzene is also used to make some types of rubbers, lubricants, dyes, detergents, drugs, and pesticides. Natural sources of benzene include emissions from volcanoes and forest fires. Benzene is also a natural part of crude oil, gasoline, and cigarette smoke.

What happens to benzene when it enters the environment?

- Industrial processes are the main source of benzene in the environment.
- Benzene can pass into the air from water and soil.
- It reacts with other chemicals in the air and breaks down within a few days.
- Benzene in the air can attach to rain or snow and be carried back down to the ground.

- It breaks down more slowly in water and soil, and can pass through the soil into underground water.
- Benzene does not build up in plants or animals.

How might I be exposed to benzene?

- Outdoor air contains low levels of benzene from tobacco smoke, automobile service stations, exhaust from motor vehicles, and industrial emissions.
- Vapors (or gases) from products that contain benzene, such as glues, paints, furniture wax, and detergents, can also be a source of exposure.
- Air around hazardous waste sites or gas stations will contain higher levels of benzene.
- Working in industries that make or use benzene.

How can benzene affect my health?

Breathing very high levels of benzene can result in death, while high levels can cause drowsiness, dizziness, rapid heart rate, headaches, tremors, confusion, and unconsciousness. Eating or drinking foods containing high levels of benzene can cause vomiting, irritation of the stomach, dizziness, sleepiness, convulsions, rapid heart rate, and death.

The major effect of benzene from long-term exposure is on the blood. Benzene causes harmful effects on the bone

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

marrow and can cause a decrease in red blood cells leading to anemia. It can also cause excessive bleeding and can affect the immune system, increasing the chance for infection.

Some women who breathed high levels of benzene for many months had irregular menstrual periods and a decrease in the size of their ovaries, but we do not know for certain that benzene caused the effects. It is not known whether benzene will affect fertility in men.

How likely is benzene to cause cancer?

Long-term exposure to high levels of benzene in the air can cause leukemia, particularly acute myelogenous leukemia, often referred to as AML. This is a cancer of the blood-forming organs. The Department of Health and Human Services (DHHS) has determined that benzene is a known carcinogen. The International Agency for Research on Cancer (IARC) and the EPA have determined that benzene is carcinogenic to humans.

How can benzene affect children?

Children can be affected by benzene exposure in the same ways as adults. It is not known if children are more susceptible to benzene poisoning than adults.

Benzene can pass from the mother's blood to a fetus. Animal studies have shown low birth weights, delayed bone formation, and bone marrow damage when pregnant animals breathed benzene.

How can families reduce the risks of exposure to benzene?

Benzene exposure can be reduced by limiting contact with gasoline and cigarette smoke. Families are encouraged not to

smoke in their house, in enclosed environments, or near their children.

Is there a medical test to determine whether I've been exposed to benzene?

Several tests can show if you have been exposed to benzene. There is a test for measuring benzene in the breath; this test must be done shortly after exposure. Benzene can also be measured in the blood; however, since benzene disappears rapidly from the blood, this test is only useful for recent exposures.

In the body, benzene is converted to products called metabolites. Certain metabolites can be measured in the urine. The metabolite S-phenylmercapturic acid in urine is a sensitive indicator of benzene exposure. However, this test must be done shortly after exposure and is not a reliable indicator of how much benzene you have been exposed to, since the metabolites may be present in urine from other sources.

Has the federal government made recommendations to protect human health?

The EPA has set the maximum permissible level of benzene in drinking water at 5 parts benzene per billion parts of water (5 ppb).

The Occupational Safety and Health Administration (OSHA) has set limits of 1 part benzene per million parts of workplace air (1 ppm) for 8 hour shifts and 40 hour work weeks.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about di(2-ethylhexyl) phthalate (DEHP). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Di(2-ethylhexyl) phthalate (DEHP) is found in many plastics. Exposure to DEHP is generally very low. Increased exposures may come from intravenous fluids delivered through plastic tubing, and from ingesting contaminated foods or water. DEHP is not toxic at the low levels usually present in the environment. In animals, high levels of DEHP damaged the liver and kidney and affected the ability to reproduce. DEHP has been found in at least 733 of the 1,613 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is di(2-ethylhexyl) phthalate?

Di(2-ethylhexyl) phthalate (DEHP) is a manufactured chemical that is commonly added to plastics to make them flexible. DEHP is a colorless liquid with almost no odor.

DEHP is present in plastic products such as wall coverings, tablecloths, floor tiles, furniture upholstery, shower curtains, garden hoses, swimming pool liners, rainwear, baby pants, dolls, some toys, shoes, automobile upholstery and tops, packaging film and sheets, sheathing for wire and cable, medical tubing, and blood storage bags.

What happens to DEHP when it enters the environment?

- DEHP is everywhere in the environment because of its use in plastics, but it does not evaporate easily or dissolve in water easily.
- DEHP can be released in small amounts to indoor air from plastic materials, coatings, and flooring.
- It dissolves faster in water if gas, oil, or paint removers are present.
- It attaches strongly to soil particles.
- DEHP in soil or water can be broken down by microorganisms into harmless compounds.

- DEHP does not break down easily when it is deep in the soil or at the bottom of lakes or rivers.
- It is in plants, fish, and other animals, but animals high on the food chain are able to break down DEHP, so tissue levels are usually low.

How might I be exposed to DEHP?

DEHP is usually present at very low levels in:

- Medical products packaged in plastic such as blood products.
- Some foods packaged in plastics, especially fatty foods like milk products, fish or seafood, and oils.
- Well water near waste sites.
- Workplace air or indoor air where DEHP is released, but usually not at levels of concern.
- Fluids from plastic intravenous tubing if used extensively as for kidney dialysis.

How can DEHP affect my health?

At the levels found in the environment, DEHP is not expected to cause harmful health effects in humans. Most of what we know about the health effects of DEHP comes from studies of rats and mice given high amounts of DEHP.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Harmful effects in animals generally occurred only with high amounts of DEHP or with prolonged exposures. Moreover, absorption and breakdown of DEHP in humans is different than in rats or mice, so the effects seen in rats and mice may not occur in humans.

Rats that breathed DEHP in the air showed no serious harmful effects. Their lifespan and ability to reproduce were not affected.

Brief oral exposure to very high levels of DEHP damaged sperm in mice. Although the effect reversed when exposure ceased, sexual maturity was delayed in the animals.

High amounts of DEHP damaged the liver of rats and mice. Whether or not DEHP contributes to human kidney damage is unclear.

Skin contact with products containing DEHP will probably cause no harmful effects because it cannot be taken up easily through the skin.

How likely is DEHP to cause cancer?

The Department of Health and Human Services (DHHS) has determined that DEHP may reasonably be anticipated to be a human carcinogen. The EPA has determined that DEHP is a probable human carcinogen. These determinations were based entirely on liver cancer in rats and mice. The International Agency for Research on Cancer (IARC) has stated that DEHP cannot be classified as to its carcinogenicity to humans.

How can DEHP affect children?

Children can be exposed to DEHP in the same manner as adults. In addition, small children can be exposed by sucking on or skin contact with plastic toys and pacifiers that contain DEHP, but there is no conclusive evidence of adverse health effects after such exposures. Nonetheless, because of concern for children's health, many toy

manufacturers have discontinued use of DEHP in their products. In pregnant rats and mice exposed to high amounts of DEHP, researchers observed birth defects and fetal deaths.

How can families reduce the risk of exposure to DEHP?

- It is almost impossible to completely avoid contact with some DEHP because it is commonly found in plastics.
- Prevent babies and small children from chewing on plastic objects not designed for that purpose.

Is there a medical test to show whether I've been exposed to DEHP?

There is a test available that measures a breakdown product of DEHP called mono(2-ethylhexyl) phthalate (MEHP) in your urine or blood. This test can only detect recent exposure because DEHP is rapidly broken down and eliminated from your body. This test is not routinely available at the doctor's office because it requires special equipment.

Has the federal government made recommendations to protect human health?

The EPA limits the amount of DEHP that may be present in drinking water to 6 parts of DEHP per billion parts of water (6 ppb).

The Occupational Safety and Health Administration (OSHA) sets a maximum average of 5 milligrams of DEHP per cubic meter of air (5 mg/m³) in the workplace during an 8-hour shift. The short-term (15-minute) exposure limit is 10 mg/m³.

Agency for Toxic Substances and Disease Registry (ATSDR). 2002. Toxicological Profile for Di(2-ethylhexyl) phthalate (Update). Atlanta, GA: U.S. Department of Health and Human Services, Public Health Service.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about bromodichloromethane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Most bromodichloromethane is formed as a by-product when chlorine is added to water-supply systems. Bromodichloromethane is not known to cause adverse health effects in people, but animal studies show that high concentrations can damage the liver and kidneys and affect the brain. Bromodichloromethane has been found at 5 of the 1,518 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is bromodichloromethane?

(Pronounced brō'mō di-klōr'ō mēth'ān')

Bromodichloromethane is a colorless, nonflammable liquid. Small amounts are formed naturally by algae in the oceans. Some of it will dissolve in water, but it readily evaporates into air.

Only small quantities of bromodichloromethane are produced in the United States. The small quantities that are produced are used in laboratories or to make other chemicals. However, most bromodichloromethane is formed as a by-product when chlorine is added to drinking water to kill bacteria.

What happens to bromodichloromethane when it enters the environment?

- Bromodichloromethane released to air is slowly broken down by reactions with other chemicals and sunlight or it can be removed by rain.
- In water, it will evaporate to the air and/or be broken down slowly by bacteria.

- When released to soil, most will evaporate to the air but some of it will be broken down by bacteria.
- Some bromodichloromethane may filter into the groundwater.
- Bromodichloromethane does not build up in the food chain.

How might I be exposed to bromodichloromethane?

- The most likely way people are exposed to bromodichloromethane is by drinking chlorinated water.
- You may breathe vapors released from chlorinated water in a swimming pool or in the home (cooking, washing dishes, bathing, etc.).
- Some bromodichloromethane may enter your body directly through your skin when bathing or swimming.
- People who live near a waste site containing bromodichloromethane could be exposed by drinking contaminated groundwater or breathing vapors released to the air.
- People who work at or live near a laboratory or factory that makes or uses this chemical could be exposed by breathing bromodichloromethane in the air.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

How can bromodichloromethane affect my health?

No studies are available regarding health effects in people exposed to bromodichloromethane.

Animal studies indicate that the liver, kidney, and central nervous system are affected by exposure to bromodichloromethane. The effects of high doses on the central nervous system include sleepiness and incoordination. Longer exposure to lower doses causes damage to the liver and kidneys. There is some evidence from animal studies that bromodichloromethane may cause birth defects at doses high enough to make the mother sick. It is not known if lower doses would cause birth defects.

How likely is bromodichloromethane to cause cancer?

There is evidence that eating or drinking bromodichloromethane causes liver, kidney, and intestinal cancer in rats and mice. The Department of Health and Human Services (DHHS) has determined that bromodichloromethane is reasonably anticipated to be a human carcinogen.

Is there a medical test to show whether I've been exposed to bromodichloromethane?

Methods are available to measure low levels of bromodichloromethane in human blood, breath, urine, and fat, but not enough information is available to use such tests to predict if any health effects might occur. Because special equipment is needed, these tests are not usually done in the doctor's office.

Has the federal government made recommendations to protect human health?

The EPA has set a Maximum Contaminant Level (MCL) of 0.1 parts per million (ppm) for the combination of bromodichloromethane and a group of similar compounds (called trihalomethanes) that occur in chlorinated water. The EPA recommends that levels of halomethanes in lakes and streams should be limited to 0.19 ppm to prevent possible health effects from drinking water or eating fish contaminated with this group of chemicals.

Any release to the environment greater than 5,000 pounds of bromodichloromethane must be reported to the EPA.

The federal recommendations have been updated as of July 1999.

Glossary

Carcinogen: A substance that can cause cancer.

CAS: Chemical Abstracts Service.

Evaporate: To change into a vapor or a gas.

National Priorities List: A list of the nation's worst hazardous waste sites.

ppm: Parts per million.

This fact sheet answers the most frequently asked health questions (FAQs) about bromoform and dibromochloromethane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because these substances may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Bromoform and dibromochloromethane are formed as by-products when chlorine is added to water supply systems. High levels of bromoform or dibromochloromethane can damage the liver and kidneys and affect the brain. Bromoform has been found in at least 140 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA). Dibromochloromethane has been found in at least 174 NPL sites.

What are bromoform and dibromochloromethane?

Bromoform and dibromochloromethane are colorless to yellow, heavy, nonflammable, liquids with a sweet odor. Small amounts are formed naturally by plants in the ocean. They are somewhat soluble in water and readily evaporate into the air. Most of the bromoform and dibromochloromethane that enters the environment is formed as byproducts when chlorine is added to drinking water to kill bacteria.

Only small quantities of bromoform and dibromochloromethane currently are produced in the United States. These chemicals were used in the past as solvents and flame retardants, or to make other chemicals, but now they are used mainly as laboratory reagents.

What happens to bromoform and dibromochloromethane when they enter the environment?

- When released to air, bromoform and dibromochloromethane are slowly broken down by reactions with other chemicals and sunlight or can be removed by rain.
- In water, these chemicals will evaporate to the air and/or be broken down slowly by bacteria.
- When released to soil, most will evaporate to the air, some will be broken down by bacteria, and some may filter into the groundwater.
- Bromoform and dibromomethane do not build up in the food chain.

How might I be exposed to bromoform and dibromochloromethane?

- The most likely way people are exposed to bromoform and dibromochloromethane is by drinking chlorinated water.
- You may breathe vapors released from chlorinated water in a swimming pool or during showering and bathing.
- Very small amounts of bromoform and dibromochloromethane may enter your body directly through your skin while bathing or swimming.
- People that live near a waste site containing bromoform or dibromochloromethane could be exposed by drinking contaminated groundwater or breathing vapors released to the air.
- Exposure could occur by breathing bromoform and dibromochloromethane in the air in or near a laboratory or factory that makes or uses these chemicals; however, this is unlikely for most people.

How can bromoform and dibromochloromethane affect my health?

Eating or breathing a large amount of bromoform slows down the normal brain activities and causes sleepiness; this tends to go away within a day. Exposure to very high amounts may cause unconsciousness and even death. No studies are available about health effects in people exposed to dibromochloromethane.

Animals exposed to high amounts of bromoform or dibromochloromethane developed liver and kidney injuries. Exposure to low levels of bromoform or

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

dibromochloromethane do not appear to seriously affect the brain, liver, or kidneys. We do not know if bromoform or dibromochloromethane affect fertility in humans, but studies in animals suggest that the risk of doing so is low.

How likely are bromoform and dibromochloromethane to cause cancer?

There is no conclusive evidence that bromoform or dibromochloromethane cause cancer in humans because no cancer studies of humans exposed exclusively to these chemicals are available. Studies in animals indicate that long-term intake of either bromoform or dibromochloromethane can cause liver and kidney cancer.

The International Agency for Research on Cancer (IARC) concluded that bromoform and dibromochloromethane are not classifiable as to human carcinogenicity. The EPA classified bromoform as a probable human carcinogen and dibromochloromethane as a possible human carcinogen.

How can bromoform and dibromochloromethane affect children?

The only information regarding effects of bromoform on the health of children is that from the early 1900s when this chemical was used as a sedative to treat children with whooping cough. In some cases of overdosing with extremely high doses, children appeared drowsy, then lifeless, just before dying. We do not know whether children are more susceptible to the effects of bromoform and dibromochloromethane than adults.

How can families reduce the risks of exposure to bromoform and dibromochloromethane?

- Families can reduce their exposure to bromoform and dibromochloromethane from tap water by installing commercially available filter systems at home.
- While bromoform is no longer used as a medicine, keeping children away from, or supervising children with, chemicals brought into the home, will reduce the potential for accidental exposures.

- Families can reduce their exposure by taking shorter baths or showers in water in which these chemicals are present and opening bathroom windows or using ceiling ventilation fans whenever possible.

Is there a medical test to determine whether I've been exposed to bromoform and dibromochloromethane?

Tests are available to measure levels of these chemicals and their breakdown products in samples of your blood, breath, or fat. These tests are not routinely available in a doctor's office because they require special equipment. Because bromoform and dibromochloromethane are eliminated from the body fairly quickly, these tests are only effective in detecting recent exposures (within 1 or 2 days at the most).

Has the federal government made recommendations to protect human health?

The EPA recommends that drinking water contain no more than 0.7 parts per million (0.7 ppm) of bromoform and 0.7 ppm of dibromochloromethane.

The Occupational Safety and Health Administration (OSHA) set a limit of 0.5 ppm for the level of bromoform in workplace air during an 8-hour workday, 40-hour work week. Because dibromochloromethane has such a limited use, OSHA has not set limits of exposure for workplace air.

This fact sheet answers the most frequently asked health questions (FAQs) about carbon tetrachloride. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Carbon tetrachloride does not occur naturally. Exposure to this substance results mostly from breathing air, drinking water, or coming in contact with soil that is contaminated with it. Exposure to very high amounts of carbon tetrachloride can damage the liver, kidneys, and nervous system. Carbon tetrachloride can cause cancer in animals. Carbon tetrachloride has been found in at least 425 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is carbon tetrachloride?

Carbon tetrachloride is a manufactured chemical that does not occur naturally. It is a clear liquid with a sweet smell that can be detected at low levels. It is also called carbon chloride, methane tetrachloride, perchloromethane, tetrachloroethane, or benziform.

Carbon tetrachloride is most often found in the air as a colorless gas. It is not flammable and does not dissolve in water very easily. It was used in the production of refrigeration fluid and propellants for aerosol cans, as a pesticide, as a cleaning fluid and degreasing agent, in fire extinguishers, and in spot removers. Because of its harmful effects, these uses are now banned and it is only used in some industrial applications.

What happens to carbon tetrachloride when it enters the environment?

- It moves very quickly into the air upon release, so most of it is in the air.
- It evaporates quickly surface water.
- Only a small amount sticks to soil particles; the rest evaporates or moves into the groundwater.
- It is very stable in air (lifetime 30-100 years).
- It can be broken down or transformed in soil and water within several days.
- When it does break down, it forms chemicals that can destroy ozone in the upper atmosphere.
- It does not build up in animals. We do not know if it build up in plants.

How might I be exposed to carbon tetrachloride?

- Breathing contaminated air near manufacturing plants or waste sites.
- Breathing workplace air when it is used.
- Drinking contaminated water near manufacturing plants and waste sites.
- Breathing contaminated air and skin contact with water while showering or cooking with contaminated water.
- Swimming or bathing in contaminated water.
- Contact with or eating contaminated soil (pica child) at waste sites.

How can carbon tetrachloride affect my health?

High exposure to carbon tetrachloride can cause liver, kidney, and central nervous system damage. These effects can occur after ingestion or breathing carbon tetrachloride, and possibly from exposure to the skin. The liver is especially sensitive to carbon tetrachloride because it enlarges and cells are damaged or destroyed. Kidneys also are damaged, causing a build up of wastes in the blood. If exposure is low and brief, the liver and kidneys can repair the damaged cells and function normally again. Effects of carbon tetrachloride are more severe in persons who drink large amounts of alcohol.

If exposure is very high, the nervous system, including the brain, is affected. People may feel intoxicated and experience headaches, dizziness, sleepiness, and nausea and vomiting. These effects may subside if exposure is stopped, but in severe cases, coma and even death may occur.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

There have been no studies of the effects of carbon tetrachloride on reproduction in humans, but studies in rats showed that long-term inhalation may cause decreased fertility.

How likely is carbon tetrachloride to cause cancer?

Studies in humans have not been able to determine whether or not carbon tetrachloride can cause cancer because usually there has been exposure to other chemicals at the same time. Swallowing or breathing carbon tetrachloride for years caused liver tumors in animals. Mice that breathed carbon tetrachloride also developed tumors of the adrenal gland. The Department of Health and Human Services (DHHS) has determined that carbon tetrachloride may reasonably be anticipated to be a carcinogen. The International Agency for Research on Cancer (IARC) has determined that carbon tetrachloride is possibly carcinogenic to humans, whereas the EPA determined that carbon tetrachloride is a probable human carcinogen.

How can carbon tetrachloride affect children?

The health effects of carbon tetrachloride have not been studied in children, but they are likely to be similar to those seen in adults exposed to the chemical. We do not know whether children differ from adults in their susceptibility to carbon tetrachloride.

A few survey-type studies suggest that maternal drinking water exposure to carbon tetrachloride might possibly be related to certain birth defects. Studies in animals showed that carbon tetrachloride can cause early fetal deaths, but did not cause birth defects. A study with human breast milk in a test tube suggested that it would be possible for carbon tetrachloride to pass from the maternal circulation to breast milk, but there is no direct demonstration of this occurring.

How can families reduce the risks of exposure to carbon tetrachloride?

- Discard any product that contains carbon tetrachloride that you may have at home and may have used in the past.
- Household chemicals should be stored out of the reach of children in their original containers.

Sometimes older children sniff household chemical products to get high. Talk to your children about the dangers of sniffing chemicals.

Is there a medical test to determine whether I've been exposed to carbon tetrachloride?

Several sensitive and specific tests are available to measure carbon tetrachloride in exposed persons. The most convenient way is simply to measure carbon tetrachloride in the exhaled air. Carbon tetrachloride also can be measured in blood, fat, or other tissues. These tests are not usually done in the doctor's office because they require special equipment. Although these tests can show that a person has been exposed to carbon tetrachloride, the results cannot be used to reliably predict whether any adverse health effect might result. Because carbon tetrachloride leaves the body fairly quickly, these methods are best suited to detecting exposures that have occurred within the last several days.

Has the federal government made recommendations to protect human health?

The EPA has set a limit for carbon tetrachloride in drinking water of 5 parts of carbon tetrachloride per billion parts of water (5 ppb). The EPA has also set limits on how much carbon tetrachloride can be released from an industrial plant into waste water and is preparing to set limits on how much carbon tetrachloride can escape from an industrial plant into outside air.

The Occupational Safety and Health Administration (OSHA) set a limit of 10 ppm for carbon tetrachloride in workplace air for an 8-hour workday, 40-hour workweek.

Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about chloroform. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to chloroform can occur when breathing contaminated air or when drinking or touching the substance or water containing it. Breathing chloroform can cause dizziness, fatigue, and headaches. Breathing chloroform or ingesting chloroform over long periods of time may damage your liver and kidneys. It can cause sores if large amounts touch your skin. This substance has been found in at least 717 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is chloroform?

(Pronounced klôr'ə-fôrm')

Chloroform is a colorless liquid with a pleasant, nonirritating odor and a slightly sweet taste. It will burn only when it reaches very high temperatures.

In the past, chloroform was used as an inhaled anesthetic during surgery, but it isn't used that way today. Today, chloroform is used to make other chemicals and can also be formed in small amounts when chlorine is added to water.

Other names for chloroform are trichloromethane and methyl trichloride.

What happens to chloroform when it enters the environment?

- Chloroform evaporates easily into the air.
- Most of the chloroform in air breaks down eventually, but it is a slow process.
- The breakdown products in air include phosgene and hydrogen chloride, which are both toxic.
- It doesn't stick to soil very well and can travel through soil to groundwater.

- Chloroform dissolves easily in water and some of it may break down to other chemicals.
- Chloroform lasts a long time in groundwater.
- Chloroform doesn't appear to build up in great amounts in plants and animals.

How might I be exposed to chloroform?

- Drinking water or beverages made using water containing chloroform.
- Breathing indoor or outdoor air containing it, especially in the workplace.
- Eating food that contains it.
- Skin contact with chloroform or water that contains it, such as in swimming pools.

How can chloroform affect my health?

Breathing about 900 parts of chloroform per million parts air (900 ppm) for a short time can cause dizziness, fatigue, and headache. Breathing air, eating food, or drinking water containing high levels of chloroform for long periods of time may damage your liver and kidneys. Large amounts of chloroform can cause sores when chloroform touches your skin.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

It isn't known whether chloroform causes reproductive effects or birth defects in people.

Animal studies have shown that miscarriages occurred in rats and mice that breathed air containing 30 to 300 ppm chloroform during pregnancy and also in rats that ate chloroform during pregnancy. Offspring of rats and mice that breathed chloroform during pregnancy had birth defects. Abnormal sperm were found in mice that breathed air containing 400 ppm chloroform for a few days.

How likely is chloroform to cause cancer?

The Department of Health and Human Services (DHHS) has determined that chloroform may reasonably be anticipated to be a carcinogen.

Rats and mice that ate food or drank water with chloroform developed cancer of the liver and kidneys.

Is there a medical test to show whether I've been exposed to chloroform?

Although the amounts of chloroform in the air that you exhale and in blood, urine, and body tissues can be measured, there is no reliable test to determine how much chloroform you have been exposed to or whether you will experience any harmful effects.

The measurement of chloroform in body fluids and tissues may help to determine if you have come into contact with large amounts of chloroform, but these tests are useful for only a short time after you are exposed. Chloroform in your body might also indicate that you have come into contact with other chemicals.

Has the federal government made recommendations to protect human health?

The EPA drinking water limit for total trihalomethanes, a class of chemicals that includes chloroform, is 100 micrograms per liter of water (100 µg/L).

The EPA requires that spills or accidental releases of 10 pounds or more of chloroform into the environment be reported to the EPA.

The Occupational Safety and Health Administration (OSHA) has set the maximum allowable concentration of chloroform in workroom air during an 8-hour workday in a 40-hour workweek at 50 ppm.

Glossary

Carcinogenicity: A substance with the ability to cause cancer.

CAS: Chemical Abstracts Service.

Ingesting: Taking food or drink into your body.

Microgram (µg): One millionth of a gram.

Miscarriage: Pregnancy loss.

ppm: Parts per million.

This ToxFAQs information is taken from the 1997 Toxicological Profile for Chloroform (update) produced by the Agency for Toxic Substances and Disease Registry, Public Health Service, U.S. Department of Health and Human Services, Public Health Service in Atlanta, GA.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html> ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about cobalt. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: The general population is exposed to low levels of cobalt in air, water, and food. Cobalt has both beneficial and harmful effects on health. At low levels, it is part of vitamin B12, which is essential for good health. At high levels, it may harm the lungs and heart. This chemical has been found in at least 426 of the 1,636 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is cobalt?

Cobalt is a naturally occurring element found in rocks, soil, water, plants, and animals. Cobalt is used to produce alloys used in the manufacture of aircraft engines, magnets, grinding and cutting tools, artificial hip and knee joints. Cobalt compounds are also used to color glass, ceramics and paints, and used as a drier for porcelain enamel and paints.

Radioactive cobalt is used for commercial and medical purposes. ⁶⁰Co (read as cobalt sixty) is used for sterilizing medical equipment and consumer products, radiation therapy for treating cancer patients, manufacturing plastics, and irradiating food. ⁵⁷Co is used in medical and scientific research. It takes about 5.27 years for half of ⁶⁰Co to give off its radiation and about 272 days for ⁵⁷Co; this is called the half-life.

What happens to cobalt when it enters the environment?

- Cobalt enters the environment from natural sources and the burning of coal or oil or the production of cobalt alloys.
- In the air, cobalt will be associated with particles that settle to the ground within a few days.
- Cobalt released into water or soil will stick to particles. Some cobalt compounds may dissolve.
- Cobalt cannot be destroyed. It can change form or attach to or separate from particles. Radioactive decay is a way of

decreasing the amount of radioactive cobalt in the environment.

How might I be exposed to cobalt?

- You can be exposed to low levels of cobalt by breathing air, eating food, or drinking water. Food and drinking water are the largest sources of exposure to cobalt for the general population.
- Working in industries that make or use cutting or grinding tools; mine, smelt, refine, or process cobalt metal or ores; or that produce cobalt alloys or use cobalt.
- The general population is rarely exposed to radioactive cobalt unless a person is undergoing radiation therapy. However, workers at nuclear facilities, irradiation facilities, or nuclear waste storage sites may be exposed to radiation from these sources.

How can cobalt affect my health?

Cobalt can benefit or harm human health. Cobalt is beneficial for humans because it is part of vitamin B12.

Exposure to high levels of cobalt can result in lung and heart effects and dermatitis. Liver and kidney effects have also been observed in animals exposed to high levels of cobalt.

Exposure to large amounts of radiation from radioactive cobalt can damage cells in your body from the radiation.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

You might also experience acute radiation syndrome that includes nausea, vomiting, diarrhea, bleeding, coma, and even death. This would be a rare event.

How likely is cobalt to cause cancer?

Nonradioactive cobalt has not been found to cause cancer in humans or animals following exposure in food or water. Cancer has been shown, however, in animals that breathed cobalt or when cobalt was placed directly into the muscle or under the skin. Based on the laboratory animal data, the International Agency for Research on Cancer (IARC) has determined that cobalt and cobalt compounds are possibly carcinogenic to humans.

Exposure to high levels of cobalt radiation can cause changes in the genetic materials within cells and may result in the development of some types of cancer.

How can cobalt affect children?

We do not know whether children differ from adults in their susceptibility to cobalt. However, it is likely that health effects in children would be similar those in adults. Studies in animals suggest that children may absorb more cobalt than adults from foods and liquids containing cobalt.

We do not know if exposure to cobalt will result in birth defects or other developmental effects in people. Birth defects have been observed in animals exposed to nonradioactive cobalt. Exposure to cobalt radiation can also result in developmental effects.

How can families reduce the risk of exposure to cobalt?

Children should avoid playing in soils near hazardous waste sites where cobalt may be present.

Is there a medical test to show whether I've been exposed to cobalt?

Cobalt levels can be tested in the urine and blood within a couple of days of exposure. Your doctor can take samples,

but must send them to a laboratory to be tested. The amount of cobalt in your blood or urine can be used to estimate how much cobalt you were exposed to. However, these tests cannot predict whether you will experience any health effects.

Two types of tests are available for radioactive cobalt. One is to see if you have been exposed to a large dose of radiation, and the other is to see if radioactive cobalt is in your body. The first looks for changes in blood cell counts or in your chromosomes that occur at 3 to 5 times the annual occupational dose limit. It cannot tell if the radiation came from cobalt. The second type of test involves examining your blood, feces, saliva, urine, and even your entire body. It is to see if cobalt is being excreted from or remains inside your body. Either the doctor's office collects and sends the samples to a special lab for testing, or you must go to the lab for testing.

Has the federal government made recommendations to protect human health?

The Occupational Safety and Health Administration (OSHA) has set a limit of 0.1 milligrams of nonradioactive cobalt per cubic meter of workplace air (0.1 mg/m³) for an 8-hour workday and 40-hour work week.

The Nuclear Regulatory Commission limits radioactive cobalt in workplace air to 1x10⁻⁵ microcurie per milliliter (μCi/mL) for ⁵⁷Co and 7x10⁻⁸ μCi/mL for ⁶⁰Co. EPA has set an average annual drinking water limit of 1000 picocurie per liter (pCi/L) for ⁵⁷Co or 100 pCi/L for ⁶⁰Co so the public radiation dose will not exceed 4 millirem.

Agency for Toxic Substances and Disease Registry (ATSDR). 2004. Toxicological Profile for Cobalt Atlanta, GA: U.S. Department of Health and Human Services, Public Health Service.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about copper. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Copper is a metal that occurs naturally in the environment, and also in plants and animals. Low levels of copper are essential for maintaining good health. High levels can cause harmful effects such as irritation of the nose, mouth and eyes, vomiting, diarrhea, stomach cramps, nausea, and even death. Copper has been found in at least 906 of the 1,647 National Priority Sites identified by the Environmental Protection Agency (EPA).

What is copper?

Copper is a metal that occurs naturally throughout the environment, in rocks, soil, water, and air. Copper is an essential element in plants and animals (including humans), which means it is necessary for us to live. Therefore, plants and animals must absorb some copper from eating, drinking, and breathing.

Copper is used to make many different kinds of products like wire, plumbing pipes, and sheet metal. U.S. pennies made before 1982 are made of copper, while those made after 1982 are only coated with copper. Copper is also combined with other metals to make brass and bronze pipes and faucets.

Copper compounds are commonly used in agriculture to treat plant diseases like mildew, for water treatment and, as preservatives for wood, leather, and fabrics.

What happens to copper when it enters the environment?

- Copper is released into the environment by mining, farming, and manufacturing operations and through waste water releases into rivers and lakes. Copper is also released from natural sources, like volcanoes, windblown dusts, decaying vegetation, and forest fires.
- Copper released into the environment usually attaches to particles made of organic matter, clay, soil, or sand.
- Copper does not break down in the environment. Copper

compounds can break down and release free copper into the air, water, and foods.

How might I be exposed to copper?

- You may be exposed to copper from breathing air, drinking water, eating foods, or having skin contact with copper, particulates attached to copper, or copper-containing compounds.
- Drinking water may have high levels of copper if your house has copper pipes and acidic water.
- Lakes and rivers that have been treated with copper compounds to control algae, or that receive cooling water from power plants, can have high levels of copper. Soils can also contain high levels of copper, especially if they are near copper smelting plants.
- You may be exposed to copper by ingesting copper-containing fungicides, or if you live near a copper mine or where copper is processed into bronze or brass.
- You may be exposed to copper if you work in copper mines or if you grind metals containing copper.

How can copper affect my health?

Everyone must absorb small amounts of copper every day because copper is essential for good health. High levels of copper can be harmful. Breathing high levels of copper can cause irritation of your nose and throat. Ingesting high levels of copper can cause nausea, vomiting, and diarrhea. Very-high doses of copper can cause damage to your liver and kidneys, and can even cause death.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

How likely is copper to cause cancer?

We do not know whether copper can cause cancer in humans. The EPA has determined that copper is not classifiable as to human carcinogenicity.

How can copper affect children?

Exposure to high levels of copper will result in the same type of effects in children and adults. We do not know if these effects would occur at the same dose level in children and adults. Studies in animals suggest that the young children may have more severe effects than adults, but we don't know if this would also be true in humans. There is a very small percentage of infants and children who are unusually sensitive to copper.

We do not know if copper can cause birth defects or other developmental effects in humans. Studies in animals suggest that high levels of copper may cause a decrease in fetal growth.

How can families reduce the risk of exposure to copper?

The most likely place to be exposed to copper is through drinking water, especially if your water is corrosive and you have copper pipes in your house. The best way to lower the level of copper in your drinking water is to let the water run for at least 15 seconds first thing in the morning before drinking or using it. This reduces the levels of copper in tap water dramatically.

If you work with copper, wear the necessary protective clothing and equipment, and always follow safety procedures. Shower and change your clothes before going home each day.

Is there a medical test to show whether I've been exposed to copper?

Copper is found throughout the body; in hair, nails, blood, urine, and other tissues. High levels of copper in these samples can show that you have been exposed to higher-than-normal levels of copper. These tests cannot tell whether you will experience harmful effects. Tests to measure copper levels in the body are not usually available at a doctor's office because they require special equipment, but the doctor can send samples to a specialty laboratory.

Has the federal government made recommendations to protect human health?

The EPA requires that levels of copper in drinking water be less than 1.3 mg of copper per one liter of drinking water (1.3 mg/L).

The U.S. Department of Agriculture has set the recommended daily allowance for copper at 900 micrograms of copper per day ($\mu\text{g/day}$) for people older than eight years old.

The Occupational Safety and Health Administration (OSHA) requires that levels of copper in the air in workplaces not exceed 0.1 mg of copper fumes per cubic meter of air (0.1 mg/m^3) and 1.0 mg/m^3 for copper dusts.

Agency for Toxic Substances and Disease Registry (ATSDR). 2004. Toxicological Profile for Copper. Atlanta, GA: U.S. Department of Health and Human Services, Public Health Service.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about aldrin and dieldrin. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to aldrin and dieldrin happens mostly from eating contaminated foods, such as root crops, fish, or seafood. Aldrin and dieldrin build up in the body after years of exposure and can affect the nervous system. Aldrin has been found in at least 207 of the 1,613 National Priorities List sites identified by the Environmental Protection Agency (EPA). Dieldrin has been found in at least 287 of the 1,613 sites.

What are aldrin and dieldrin?

Aldrin and dieldrin are insecticides with similar chemical structures. They are discussed together in this fact sheet because aldrin quickly breaks down to dieldrin in the body and in the environment. Pure aldrin and dieldrin are white powders with a mild chemical odor. The less pure commercial powders have a tan color. Neither substance occurs naturally in the environment.

From the 1950s until 1970, aldrin and dieldrin were widely used pesticides for crops like corn and cotton. Because of concerns about damage to the environment and potentially to human health, EPA banned all uses of aldrin and dieldrin in 1974, except to control termites. In 1987, EPA banned all uses.

What happens to aldrin and dieldrin when they enter the environment?

- Sunlight and bacteria change aldrin to dieldrin so that we mostly find dieldrin in the environment.
- They bind tightly to soil and slowly evaporate to the air.
- Dieldrin in soil and water breaks down very slowly.
- Plants take in and store aldrin and dieldrin from the soil.
- Aldrin rapidly changes to dieldrin in plants and animals.
- Dieldrin is stored in the fat and leaves the body very slowly.

How might I be exposed to aldrin or dieldrin?

- Dieldrin is everywhere in the environment, but at very low levels.

- Eating food like fish or shellfish from lakes or streams contaminated with either chemical, or contaminated root crops, dairy products, or meats.
- Air, surface water, or soil near waste sites may contain higher levels.
- Living in homes that were once treated with aldrin or dieldrin to control termites.

How can aldrin and dieldrin affect my health?

People who have intentionally or accidentally ingested large amounts of aldrin or dieldrin have suffered convulsions and some died. Health effects may also occur after a longer period of exposure to smaller amounts because these chemicals build up in the body.

Some workers exposed to moderate levels in the air for a long time had headaches, dizziness, irritability, vomiting, and uncontrolled muscle movements. Workers removed from the source of exposure rapidly recovered from most of these effects.

Animals exposed to high amounts of aldrin or dieldrin also had nervous system effects. In animals, oral exposure to lower levels for a long period also affected the liver and decreased their ability to fight infections. We do not know whether aldrin or dieldrin affect the ability of people to fight disease.

Studies in animals have given conflicting results about whether aldrin and dieldrin affect reproduction in male animals and whether these chemicals may damage the sperm.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

We do not know whether aldrin or dieldrin affect reproduction in humans.

How likely are aldrin and dieldrin to cause cancer?

There is no conclusive evidence that aldrin or dieldrin cause cancer in humans. Aldrin and dieldrin have been shown to cause liver cancer in mice. The International Agency for Research on Cancer (IARC) has determined that aldrin and dieldrin are not classifiable as to human carcinogenicity. The EPA has determined that aldrin and dieldrin are probable human carcinogens.

How can aldrin and dieldrin affect children?

Children can be exposed to aldrin and dieldrin in the same way as adults. There are no known unique exposure pathways for children. Children who swallowed amounts of aldrin or dieldrin much larger than those found in the environment suffered convulsions and some died, as occurred in adults. However, we do not know whether children are more susceptible than adults to the effects of aldrin or dieldrin.

We do not know whether aldrin or dieldrin cause birth defects in humans. Pregnant animals that ingested aldrin or dieldrin had some babies with low birth weight and some with alterations in the skeleton. Dieldrin has been found in human breast milk, therefore, it can be passed to suckling infants.

How can families reduce the risk of exposure to aldrin and dieldrin?

- Since aldrin and dieldrin are no longer produced or used, exposure to these compounds will occur only from past usage.
- Because aldrin and dieldrin were applied to the basement of some homes for termite protection, before buying a home families should investigate what, if any, pesticides have been used within the home.

Is there a medical test to show whether I've been exposed to aldrin and dieldrin?

There are laboratory tests that can measure aldrin and dieldrin in your blood, urine, and body tissues. Because aldrin changes to dieldrin fairly quickly in the body, the test has to be done shortly after you are exposed to aldrin. Since dieldrin can stay in the body for months, measurements of dieldrin can be made much longer after exposure to either aldrin or dieldrin. The tests cannot tell you whether harmful health effects will occur. These tests are not routinely available at the doctor's office because they require special equipment.

Has the federal government made recommendations to protect human health?

The EPA limits the amount of aldrin and dieldrin that may be present in drinking water to 0.001 and 0.002 milligrams per liter (mg/L) of water, respectively, for protection against health effects other than cancer. The EPA has determined that a concentration of aldrin and dieldrin of 0.0002 mg/L in drinking water limits the lifetime risk of developing cancer from exposure to each compound to 1 in 10,000.

The Occupational Safety and Health Administration (OSHA) sets a maximum average of 0.25 milligrams of aldrin and dieldrin per cubic meter of air (0.25 mg/m³) in the workplace during an 8-hour shift, 40 hour week. The National Institute for Occupational Safety and Health (NIOSH) also recommends a limit of 0.25 mg/m³ for both compounds for up to a 10-hour work day, 40-hour week.

The Food and Drug Administration (FDA) regulates the residues of aldrin and dieldrin in raw foods. The allowable range is from 0 to 0.1 ppm, depending on the type of food product.

References

Agency for Toxic Substances and Disease Registry (ATSDR). 2002. Toxicological Profile for Aldrin/Dieldrin (Update). Atlanta, GA: U.S. Department of Health and Human Services, Public Health Service.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about ethylbenzene. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Ethylbenzene is a colorless liquid found in a number of products including gasoline and paints. Breathing very high levels can cause dizziness and throat and eye irritation. Breathing lower levels has resulted in hearing effects and kidney damage in animals. Ethylbenzene has been found in at least 829 of 1,689 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is ethylbenzene?

Ethylbenzene is a colorless, flammable liquid that smells like gasoline.

It is naturally found in coal tar and petroleum and is also found in manufactured products such as inks, pesticides, and paints.

Ethylbenzene is used primarily to make another chemical, styrene. Other uses include as a solvent, in fuels, and to make other chemicals.

What happens to ethylbenzene when it enters the environment?

- Ethylbenzene moves easily into the air from water and soil.
- It takes about 3 days for ethylbenzene to be broken down in air into other chemicals.
- In surface water, ethylbenzene breaks down by reacting with other chemicals found naturally in water.
- Ethylbenzene can move through soil into groundwater
- In soil, it is broken down by bacteria.

How might I be exposed to ethylbenzene?

- If you live in a city or near many factories or heavily traveled highways, you may be exposed to ethylbenzene in air.
- Releases of ethylbenzene into the air occur from burning oil, gas, and coal and from industries using ethylbenzene.

- Ethylbenzene is not often found in drinking water. Higher levels may be found in residential drinking water wells near landfills, waste sites, or leaking underground fuel storage tanks.
- Working in an industry where ethylbenzene is used or made.
- Using products containing it, such as gasoline, carpet glues, varnishes, and paints.

How can ethylbenzene affect my health?

Exposure to high levels of ethylbenzene in air for short periods can cause eye and throat irritation. Exposure to higher levels can result in dizziness.

Irreversible damage to the inner ear and hearing has been observed in animals exposed to relatively low concentrations of ethylbenzene for several days to weeks.

Exposure to relatively low concentrations of ethylbenzene in air for several months to years causes kidney damage in animals.

How likely is ethylbenzene to cause cancer?

The International Agency for Research on Cancer (IARC) has determined that ethylbenzene is a possible human carcinogen.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

How can ethylbenzene affect children?

There are no studies evaluating the effects of ethylbenzene exposure on children or immature animals. It is likely that children would have the same health effects as adults. We do not know whether children would be more sensitive than adults to the effects of ethylbenzene.

We do not know if ethylbenzene will cause birth defects in humans. Minor birth defects and low birth weight have occurred in newborn animals whose mothers were exposed to ethylbenzene in air during pregnancy.

How can families reduce the risks of exposure to ethylbenzene?

- Use adequate ventilation to reduce exposure to ethylbenzene vapors from consumer products such as gasoline, pesticides, varnishes and paints, and newly installed carpeting.
- Sometimes older children sniff household chemicals, including ethylbenzene, in an attempt to get high. Talk with your children about the dangers of sniffing chemicals.
- Household chemicals should be stored out of reach of children to prevent accidental poisoning. Always store household chemicals in their original containers; never store them in containers that children would find attractive to eat or drink from, such as old soda bottles. Gasoline should be stored in a gasoline can with a locked cap.

Is there a medical test to determine whether I've been exposed to ethylbenzene?

Ethylbenzene is found in the blood, urine, breath, and some body tissues of exposed people. The most common way to test for ethylbenzene is in the urine. This test measures substances formed by the breakdown of ethylbenzene. Because these substances leave the body very quickly, this test needs to be done within a few hours after exposure occurs.

These tests can show you were exposed to ethylbenzene, but cannot predict the kind of health effects that might occur.

Has the federal government made recommendations to protect human health?

The EPA has determined that exposure to ethylbenzene in drinking water at concentrations of 30 ppm for 1 day or 3 ppm for 10 days is not expected to cause any adverse effects in a child.

The EPA has determined that lifetime exposure to 0.7 ppm ethylbenzene is not expected to cause any adverse effects.

The Occupational Health and Safety Administration (OSHA) has limited workers' exposure to an average of 100 ppm for an 8-hour workday, 40-hour workweek.

This fact sheet was created from information obtained from the United States Environmental Protection Agency (USEPA) Total Coliform Rule, found at <http://www.epa.gov/safewater/disinfection/tcr/index.html>. This fact sheet answers the most frequently asked health questions (FAQs) about coliforms and fecal coliforms. It is important you understand this information because these substances may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: Total coliforms and fecal coliforms are groups of bacteria used as indicators of possible sewage contamination because they are commonly found in human and animal feces. Although they are generally not harmful themselves, they indicate the possible presence of pathogenic (disease-causing) bacteria, viruses, and protozoans that also live in human and animal digestive systems. Therefore, their presence in well water suggests that pathogenic microorganisms might also be present and that drinking well water might be a health risk. Sources of fecal contamination to well water includes septic systems, domestic and wild animal manure, and storm runoff.

What are total coliforms/fecal coliforms?

Total coliforms and fecal coliforms are a group of closely related bacteria that are usually free-living in the environment, but that are also present in water contaminated with human and animal feces. In general, coliform counts give an overall indication of the sanitary condition of a water supply. Fecal coliforms are bacteria found in feces, and are a subgroup of coliforms. Fecal coliforms normally reside in the intestinal tract of warm-blooded animals. The fecal coliform group includes both pathogen (disease-causing) and nonpathogenic bacteria. The presence of fecal coliforms in drinking water indicates that disease-causing organisms may be present.

Coliform contamination can occur when increased run-off enters the drinking water source (for example, following heavy rains). It can also happen due to a break in the water distribution system (pipes), or failure of a water treatment process.

What happens to coliforms/fecal coliforms when they enter the environment?

- Coliforms are free-living bacteria that are normally found in the environment.
- Coliforms are short-lived in the environment, outside of a warm-blooded host.

How might I be exposed to total coliforms/fecal coliforms?

- Ingesting coliforms in drinking water
- Ingesting fecal contaminated foodstuffs

How can coliforms/fecal coliforms affect my health?

Most coliform bacteria do not cause illness. However, their presence in a water system is a public health concern because of the potential for disease-causing strains of bacteria, viruses, and protozoa to also be present. Symptoms from water-borne illness may include diarrhea, cramps, nausea, headaches, jaundice, or fatigue. Symptoms may appear as early as a few hours to several days after infection and may last more than two weeks.

How can coliforms/fecal coliforms affect children?

Children experience the same health effect as adults following exposure. However, they may experience more severe symptoms due to immature immune systems and due to their increased susceptibility to dehydration.

How can families reduce the risks of exposure to coliforms/fecal coliforms?

- Drinking water should be periodically tested for total coliforms/fecal coliforms.
- If your drinking water has elevated levels of total coliforms or fecal coliforms you should use cleaner sources of water.

Is there a medical test to determine whether I've been exposed to coliforms/fecal coliforms?

Coliforms and fecal coliforms are typically present in the digestive system, however a stool sample may reveal an elevated level of a pathogenic strain, or the presence of a less common strain that may be associated with illness.

Has the federal government made recommendations to protect human health?

The USEPA has set and enforceable standard called a maximum contaminant level (MCL) for coliforms and fecal coliforms of zero colony-forming units (CFUs) per 100 milliliters water. The USEPA believes that any detection of coliforms or fecal coliforms in drinking water could potentially be associated with human illness.

Where Can I Get More Information? More information on the adverse effects of fecal coliforms/total coliforms can be obtained from your community or state health or environmental quality department.

This fact sheet was created from information presented in the National Library of Medicine Hazardous Substances Data Bank. This fact sheet answers the most frequently asked health questions (FAQs) about fluoride. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: Fluorides are naturally occurring compounds. Low levels of fluorides can help prevent dental cavities. At high levels, fluorides can result in tooth and bone damage.

What is fluoride?

Fluoride is a naturally occurring element. Fluorides are often added to drinking water supplies and to a variety of dental products, including toothpaste and mouth rinses, to prevent dental cavities.

What happens to fluoride when it enters the environment?

- When fluoride is released to the air from volcanoes and industry, it is carried by wind and rain to nearby water, soil, and food sources.
- Fluorides in water and soil will form strong bonds with sediment or soil particles.
- Fluorides will accumulate in plants and animals. In animals, the fluoride accumulates primarily in the bones or shell rather than in soft tissues.

How might I be exposed to fluoride?

- The general population can be exposed to fluorides in contaminated air, food, drinking water, and soil.
- People living in communities with fluoridated water or high levels of naturally-occurring fluoride may be exposed to higher levels.
- People who work or live near industries where fluoride-containing substances are used may be exposed to higher levels.

How can fluoride affect my health?

- Small amounts of fluoride help prevent tooth cavities, but high levels can harm your health.
- In adults, exposure to high levels of fluoride can result in denser bones. However, if exposure is high enough, these bones may be more fragile and brittle and there may be a greater risk of breaking the bone.

How likely is fluoride to cause cancer?

- Most studies of people living in areas with fluoridated water or naturally high levels of fluoride in drinking water did not find an association between fluoride and cancer risks.
- Two animal cancer studies were inconclusive.
- The International Agency for Research on Cancer (IARC) has determined that the carcinogenicity of fluoride to humans is not classifiable.

How can fluoride affect children?

- When used appropriately, fluoride is both safe and effective in preventing and controlling cavities.
- Drinking or eating excessive fluoride during the time teeth are being formed (before 8 years of age) can cause visible changes in teeth. This condition is called dental fluorosis.
- At very high concentrations of fluoride, the teeth can become more fragile and sometimes can break.
- No studies have addressed whether low levels of fluoride will cause birth defects in humans. Birth defects have not been found in most studies of animals.

How can families reduce the risks of exposure to fluoride?

- ❑ In the home, children may be exposed to high levels of fluorides if they swallow dental products containing fluoridated toothpaste, gels, or rinses.
- ❑ Parents should supervise teeth brushing and place, at most, a small pea-size dab of toothpaste on the brush and teach children not to swallow dental products.
- ❑ People who live in areas with high levels of naturally-occurring fluoride in the water should use alternative sources of drinking water, such as bottled water.

Is there a medical test to determine whether I've been exposed to fluoride?

- ❑ Tests are available to measure fluoride levels in urine; these tests can determine if you have been exposed to higher-than normal levels of fluorides. The urine test must be performed soon after exposure because fluoride that is not stored in bones leaves the body within a few days. The test cannot be performed in the doctor's office, but can be done at most laboratories that test for chemical exposure.
- ❑ The urine fluoride test cannot be used to predict the nature or severity of toxic effects. Bone sampling can be done in special cases to measure long-term exposure to fluorides.

Has the federal government made recommendations to protect human health?

- ❑ The United States Environmental Protection Agency (EPA) has set a maximum amount of fluoride allowable in drinking water of 4.0 milligrams per liter of water (4.0 mg/L).
- ❑ For the prevention of dental decay, the United States Public Health Service (PHS) has, since 1962, recommended that public water supplies contain between 0.7 and 1.2 milligrams of fluoride per liter of drinking water.
- ❑ The United States Occupational Safety and Health Administration (OSHA) has set limits of 2.5 mg/m³ for fluoride in workroom air to protect workers during an 8-hour shift over a 40-hour work week.

National Library of Medicine. Hazardous Substances Data Bank. <http://toxnet.nlm.nih.gov/>

Where Can I Get More Information? More information on the adverse effects fluoride can be obtained from your community or state health or environmental quality department.

This fact sheet answers the most frequently asked health questions (FAQs) about formaldehyde. For more information, call the ATSDR Information Center at 1-800-CDC-INFO. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Everyone is exposed to small amounts of formaldehyde in air and some foods and products. Formaldehyde can cause irritation of the skin, eyes, nose, and throat. High levels of exposure may cause some types of cancers. This substance has been found in at least 26 of the 1,467 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is formaldehyde?

(Pronounced fôr-mäl/də-hid')

At room temperature, formaldehyde is a colorless, flammable gas that has a distinct, pungent smell. It is also known as methanal, methylene oxide, oxymethylene, methylaldehyde, and oxomethane. Formaldehyde is naturally produced in small amounts in our bodies.

It is used in the production of fertilizer, paper, plywood, and urea-formaldehyde resins. It is also used as a preservative in some foods and in many products used around the house, such as antiseptics, medicines, and cosmetics.

What happens to formaldehyde when it enters the environment?

- Formaldehyde dissolves easily but does not last a long time in water.
- Most formaldehyde in the air breaks down during the day.
- The breakdown products of formaldehyde are formic acid and carbon monoxide.
- Formaldehyde does not build up in plants and animals.

How might I be exposed to formaldehyde?

- Smog is a major source of formaldehyde exposure.
- Cigarettes and other tobacco products, gas cookers, and open fireplaces are sources of formaldehyde exposure.
- It is used in many industries and in hospitals and laboratories.
- Formaldehyde is given off as a gas from the manufactured wood products used in new mobile homes.
- The amount of formaldehyde in foods is very small.
- Household sources, such as fiberglass, carpets, permanent press fabrics, paper products, and some household cleaners.

How can formaldehyde affect my health?

Low levels of formaldehyde can cause irritation of the eyes, nose, throat, and skin. It is possible that people with asthma may be more sensitive to the effects of inhaled formaldehyde.

Drinking large amounts of formaldehyde can cause severe pain, vomiting, coma, and possible death.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

How likely is formaldehyde to cause cancer?

Some studies of people exposed to formaldehyde in workplace air found more cases of cancer of the nose and throat than expected, but other studies did not confirm this finding.

In animal studies, rats exposed to high levels of formaldehyde in air developed nose cancer. The Department of Health and Human Services (DHHS) has determined that formaldehyde may reasonably be anticipated to be a carcinogen.

How can formaldehyde affect children?

The most common route of exposure is by breathing it, which is likely to cause nose and eye irritation (burning, itchy, tearing, and sore throat) in children as well as in adults.

Animal studies suggest that formaldehyde will not cause birth defects in humans. It is not likely to be transferred to a child in breast milk.

How can families reduce the risk of exposure to formaldehyde?

Formaldehyde is usually found in the air, and levels are usually higher indoors than outdoors. Opening windows and using fans to bring fresh air indoors are the easiest ways to lower levels in the house. Not smoking and not using unvented heaters indoors can lower the formaldehyde levels.

Removing formaldehyde sources in the home can reduce exposure. Formaldehyde is given off from a number of products used in the home. Providing fresh air, sealing unfinished manufactured wood surfaces, and washing new permanent press clothing before wearing can help lower exposure.

Is there a medical test to show whether I've been exposed to formaldehyde?

Laboratory tests can measure formaldehyde in blood, urine, and breath. These tests do not tell you how much formaldehyde you have been exposed to or if harmful effects will occur. The tests are not routinely available at your doctor's office.

What recommendations has the federal government made to protect human health?

The EPA recommends that an adult should not drink water containing more than 1 milligram of formaldehyde per liter of water (1 mg/L) for a lifetime exposure, and a child should not drink water containing more than 10 mg/L for 1 day or 5 mg/L for 10 days.

The Occupational Safety and Health Administration (OSHA) has set a permissible exposure limit for formaldehyde of 0.75 parts per million (ppm) for an 8-hour workday, 40-hour workweek.

The National Institute for Occupational Safety and Health (NIOSH) recommends an exposure limit of 0.016 ppm.

This fact sheet answers the most frequently asked health questions (FAQs) about hexachlorobutadiene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Most exposure to hexachlorobutadiene comes from breathing it in workplace air. People living near hazardous waste sites may be exposed to it by breathing air or by drinking contaminated water. Animal studies suggest that hexachlorobutadiene can damage the kidneys and liver and may cause kidney tumors. This chemical has been found in at least 47 of 1,416 National Priorities List sites identified by the Environmental Protection Agency.

What is hexachlorobutadiene?

(Pronounced hĕk'sə klŏr' ō byŏŏ'tə-dī'ēn')

Hexachlorobutadiene is a colorless liquid with a turpentine-like odor. It is also called perchlorobutadiene. Hexachlorobutadiene is not found naturally in the environment. It is formed when other chemicals are made.

Most hexachlorobutadiene used commercially in the United States is imported from Germany. It is mainly used to make rubber compounds. It is also used as a solvent, and to make lubricants, in gyroscopes, as a heat transfer liquid, and as a hydraulic fluid.

What happens to hexachlorobutadiene when it enters the environment?

- Hexachlorobutadiene is released to the environment mainly from its disposal following industrial uses.
- In air, half of it may be broken down to other chemicals within 60 days.
- In water, half of it may be broken down to other chemicals within about 30 days.
- Hexachlorobutadiene appears to readily break down in soil.
- Hexachlorobutadiene can accumulate in fish and shellfish.

How might I be exposed to hexachlorobutadiene?

- Working in industries that make or use hexachlorobutadiene.
- Breathing air around hazardous waste sites where it has been disposed of.
- Drinking water contaminated with hexachlorobutadiene.
- Eating fish or other foods contaminated with it.

How can hexachlorobutadiene affect my health?

There are no studies that have looked at the effects of hexachlorobutadiene in people. All of our information has come from studies in animals.

Studies in mice have shown irritation of the nose when large amounts were breathed over a short time. The only other effect noted in animals from breathing hexachlorobutadiene was a reduction in the body weights of fetuses when their mothers breathed high levels of the chemical.

There are no studies which looked at animals breathing low levels of hexachlorobutadiene over a long time.

Rats and mice that drank low levels of hexachlorobutadiene over both short and long periods had kidney and

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

liver damage. No effects on reproduction or on the developing fetuses were seen when rats and mice drank hexachlorobutadiene.

Studies in rabbits found kidney and liver damage from contact with the chemical on the skin for a short time.

How likely is hexachlorobutadiene to cause cancer?

The Environmental Protection Agency (EPA) has determined that hexachlorobutadiene is a possible human carcinogen.

An animal study found kidney tumors in rats exposed to low levels of hexachlorobutadiene. It is not known whether it may also cause cancer in people.

Is there a medical test to show whether I've been exposed to hexachlorobutadiene?

Tests are available that measure levels of hexachlorobutadiene and its breakdown products in urine or fat. However, these tests must be performed within several days after exposure because hexachlorobutadiene leaves the body fairly quickly.

These tests are not usually performed in most doctors' offices because special equipment is needed to conduct them. In addition, these tests cannot determine if adverse health effects will occur from the exposure to hexachlorobutadiene.

Has the federal government made recommendations to protect human health?

EPA has recommended guidelines for exposure to hexachlorobutadiene in drinking water. EPA recommends

that exposures in children should not exceed 0.3 milligrams per liter (mg/L) for 10-day periods or more than 0.1 mg/L for longer periods (7 years). Adults should not be exposed to more than 0.4 mg/L for longer periods (7 years).

EPA requires that discharges or accidental spills into the environment of 1 pound or more of hexachlorobutadiene be reported.

The National Institute for Occupational Safety and Health (NIOSH) has recommended an occupational exposure limit of 0.02 parts hexachlorobutadiene per million parts in air (0.02 ppm) for an 8-hour workday over a 40-hour work-week.

The American Conference of Governmental Industrial Hygienists (ACGIH) has established the same guidelines as NIOSH for the workplace.

These agencies advise avoiding eye and skin contact because this may be a route of significant exposure.

Glossary

Carcinogen: A substance that can cause cancer.

Long time: Lasting one year or longer.

ppm: Parts per million.

Short time: Lasting 14 days or less.

Solvent: A substance that dissolves another substance.

Tumor: An abnormal mass of tissue.

This fact sheet answers the most frequently asked health questions (FAQs) about *n*-hexane. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: *n*-Hexane is mixed with solvents for a number of uses. Inhaling *n*-hexane causes nerve damage and paralysis of the arms and legs. Some people abuse products containing *n*-hexane by inhaling it to get "high." This substance has been found in at least 60 of the 1,467 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is *n*-hexane?

(Pronounced ěn hěk' sĀn)

n-Hexane is a chemical made from crude oil. Pure *n*-hexane is a colorless liquid with a slightly disagreeable odor. It is highly flammable, and its vapors can be explosive.

Pure *n*-hexane is used in laboratories. Most of the *n*-hexane used in industry is mixed with similar chemicals called solvents. The major use for solvents containing *n*-hexane is to extract vegetable oils from crops such as soybeans.

These solvents are also used as cleaning agents in the printing, textile, furniture, and shoemaking industries. Certain kinds of special glues used in the roofing and shoe and leather industries also contain *n*-hexane. Several consumer products contain *n*-hexane, such as gasoline, quick-drying glues used in various hobbies, and rubber cement.

What happens to *n*-hexane when it enters the environment?

- n*-Hexane enters the environment during its manufacture and use.

- It evaporates very easily into the air where it is broken down in a few days.
- It dissolves only slightly in water.
- Most of *n*-hexane spilled in water will float on the surface where it evaporates into the air.
- If *n*-hexane is spilled on the ground, most of it will evaporate before it can soak into the soil.
- n*-Hexane is not concentrated by plants, fish, or animals.

How might I be exposed to *n*-hexane?

- You are most likely to be exposed to *n*-hexane by breathing in air contaminated with it.
- You may be exposed if you use products containing it at work.
- Since it is in gasoline, nearly everyone is exposed to very small amounts of *n*-hexane in the air.
- Exposure can occur at home if you use products containing *n*-hexane without proper ventilation.

How can *n*-hexane affect my health?

The only people known to have been affected by exposure to *n*-hexane used it at work. Breathing large amounts caused numbness in the feet and hands, followed by muscle

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

weakness in the feet and lower legs. Continued exposure led to paralysis of the arms and legs. If removed from the exposure, the workers recovered in 6 months to a year.

In laboratory studies, animals exposed to high levels of *n*-hexane in air had signs of nerve damage. Some animals also had lung damage. In other studies, rats exposed to very high levels of *n*-hexane had damage to sperm-forming cells.

How likely is *n*-hexane to cause cancer?

There is no evidence that *n*-hexane causes cancer in people or animals.

The Department of Health and Human Services (DHHS), International Agency for Research on Cancer (IARC) and the EPA have not classified *n*-hexane for carcinogenicity.

How can *n*-hexane affect children?

Since most exposure occurs at work, children aren't likely to be exposed to levels of *n*-hexane that cause problems. We don't know if the effects seen in children would be different than those seen in adults.

Sometimes older children inhale or "sniff" household chemicals in an attempt to get "high." This has caused paralysis of the arms and legs of teenagers in the U.S. and Europe.

How can families reduce the risk of exposure to *n*-hexane?

- Teach your children and teenagers the dangers of inhaling products that contain *n*-hexane.
- Keep products containing *n*-hexane (quick-drying glues and cements) out of the reach of children.

- Maintain proper ventilation when using these products.
- Never store household chemicals in containers, such as old soda bottles, that children might find attractive.

Is there a medical test to show whether I've been exposed to *n*-hexane?

If you have been exposed to harmful amounts of *n*-hexane, the amount of one of its breakdown products will probably be increased in your urine. Your doctor can send a sample to a specialized laboratory. This test can only detect *n*-hexane exposure that occurred within 2 to 3 days of testing.

Has the federal government made recommendations to protect human health?

The EPA requires that spills or accidental releases of 5,000 pounds or more of *n*-hexane be reported to the EPA.

The National Institute of Occupational Safety and Health (NIOSH) recommends exposure to no more than 50 parts per million (ppm) in workplace air. The Occupational Health and Safety Administration (OSHA) has set a permissible exposure limit of 500 ppm for *n*-hexane in workplace air.

This fact sheet answers the most frequently asked health questions (FAQs) about lead. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to lead can happen from breathing workplace air or dust, eating contaminated foods, or drinking contaminated water. Children can be exposed from eating lead-based paint chips or playing in contaminated soil. Lead can damage the nervous system, kidneys, and reproductive system. Lead has been found in at least 1,272 of the 1,684 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is lead?

Lead is a naturally occurring bluish-gray metal found in small amounts in the earth's crust. Lead can be found in all parts of our environment. Much of it comes from human activities including burning fossil fuels, mining, and manufacturing.

Lead has many different uses. It is used in the production of batteries, ammunition, metal products (solder and pipes), and devices to shield X-rays. Because of health concerns, lead from paints and ceramic products, caulking, and pipe solder has been dramatically reduced in recent years. The use of lead as an additive to gasoline was banned in 1996 in the United States.

What happens to lead when it enters the environment?

- Lead itself does not break down, but lead compounds are changed by sunlight, air, and water.
- When lead is released to the air, it may travel long distances before settling to the ground.
- Once lead falls onto soil, it usually sticks to soil particles.
- Movement of lead from soil into groundwater will depend on the type of lead compound and the characteristics of the soil.

How might I be exposed to lead?

- Eating food or drinking water that contains lead. Water pipes in some older homes may contain lead solder. Lead can leach out into the water.

- Spending time in areas where lead-based paints have been used and are deteriorating. Deteriorating lead paint can contribute to lead dust.

- Working in a job where lead is used or engaging in certain hobbies in which lead is used, such as making stained glass.

- Using health-care products or folk remedies that contain lead.

How can lead affect my health?

The effects of lead are the same whether it enters the body through breathing or swallowing. Lead can affect almost every organ and system in your body. The main target for lead toxicity is the nervous system, both in adults and children. Long-term exposure of adults can result in decreased performance in some tests that measure functions of the nervous system. It may also cause weakness in fingers, wrists, or ankles. Lead exposure also causes small increases in blood pressure, particularly in middle-aged and older people and can cause anemia. Exposure to high lead levels can severely damage the brain and kidneys in adults or children and ultimately cause death. In pregnant women, high levels of exposure to lead may cause miscarriage. High-level exposure in men can damage the organs responsible for sperm production.

How likely is lead to cause cancer?

We have no conclusive proof that lead causes cancer in humans. Kidney tumors have developed in rats and mice that had been given large doses of some kind of lead compounds. The Department of Health and Human Services

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

(DHHS) has determined that lead and lead compounds are reasonably anticipated to be human carcinogens and the EPA has determined that lead is a probable human carcinogen. The International Agency for Research on Cancer (IARC) has determined that inorganic lead is probably carcinogenic to humans and that there is insufficient information to determine whether organic lead compounds will cause cancer in humans.

How can lead affect children?

Small children can be exposed by eating lead-based paint chips, chewing on objects painted with lead-based paint, or swallowing house dust or soil that contains lead.

Children are more vulnerable to lead poisoning than adults. A child who swallows large amounts of lead may develop blood anemia, severe stomachache, muscle weakness, and brain damage. If a child swallows smaller amounts of lead, much less severe effects on blood and brain function may occur. Even at much lower levels of exposure, lead can affect a child's mental and physical growth.

Exposure to lead is more dangerous for young and unborn children. Unborn children can be exposed to lead through their mothers. Harmful effects include premature births, smaller babies, decreased mental ability in the infant, learning difficulties, and reduced growth in young children. These effects are more common if the mother or baby was exposed to high levels of lead. Some of these effects may persist beyond childhood.

How can families reduce the risks of exposure to lead?

- Avoid exposure to sources of lead.
- Do not allow children to chew on mouth surfaces that may have been painted with lead-based paint.
- If you have a water lead problem, run or flush water that has been standing overnight before drinking or cooking with it.
- Some types of paints and pigments that are used as make-up or hair coloring contain lead. Keep these kinds of products away from children
- If your home contains lead-based paint or you live in an area contaminated with lead, wash children's hands and faces

often to remove lead dusts and soil, and regularly clean the house of dust and tracked in soil.

Is there a medical test to determine whether I've been exposed to lead?

A blood test is available to measure the amount of lead in your blood and to estimate the amount of your recent exposure to lead. Blood tests are commonly used to screen children for lead poisoning. Lead in teeth or bones can be measured by X-ray techniques, but these methods are not widely available. Exposure to lead also can be evaluated by measuring erythrocyte protoporphyrin (EP) in blood samples. EP is a part of red blood cells known to increase when the amount of lead in the blood is high. However, the EP level is not sensitive enough to identify children with elevated blood lead levels below about 25 micrograms per deciliter ($\mu\text{g}/\text{dL}$). These tests usually require special analytical equipment that is not available in a doctor's office. However, your doctor can draw blood samples and send them to appropriate laboratories for analysis.

Has the federal government made recommendations to protect human health?

The Centers for Disease Control and Prevention (CDC) recommends that states test children at ages 1 and 2 years. Children should be tested at ages 3–6 years if they have never been tested for lead, if they receive services from public assistance programs for the poor such as Medicaid or the Supplemental Food Program for Women, Infants, and Children, if they live in a building or frequently visit a house built before 1950; if they visit a home (house or apartment) built before 1978 that has been recently remodeled; and/or if they have a brother, sister, or playmate who has had lead poisoning. CDC considers a blood lead level of 10 $\mu\text{g}/\text{dL}$ to be a level of concern for children.

EPA limits lead in drinking water to 15 μg per liter.

This fact sheet answers the most frequently asked health questions (FAQs) about methyl *tert*-butyl ether (MTBE). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Methyl *tert*-butyl ether (MTBE) is a flammable liquid which is used as an additive in unleaded gasoline. Drinking or breathing MTBE may cause nausea, nose and throat irritation, and nervous system effects. MTBE has been found in at least 11 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is methyl *tert*-butyl ether?

(Pronounced məth'əl tūr'shē-ēr'ē byōōt'l ē'thər)

Methyl *tert*-butyl ether (MTBE) is a flammable liquid with a distinctive, disagreeable odor. It is made from blending chemicals such as isobutylene and methanol, and has been used since the 1980s as an additive for unleaded gasolines to achieve more efficient burning.

MTBE is also used to dissolve gallstones. Patients treated in this way have MTBE delivered directly to their gall bladders through special tubes that are surgically inserted.

What happens to MTBE when it enters the environment?

- MTBE quickly evaporates from open containers and surface water, so it is commonly found as a vapor in the air.
- Small amounts of MTBE may dissolve in water and get into underground water.
- It remains in underground water for a long time.

- MTBE may stick to particles in water, which will cause it to eventually settle to the bottom sediment.
- MTBE may be broken down quickly in the air by sunlight.
- MTBE does not build up significantly in plants and animals.

How might I be exposed to MTBE?

- Touching the skin or breathing contaminated air while pumping gasoline.
- Breathing exhaust fumes while driving a car.
- Breathing air near highways or in cities.
- Drinking, swimming, or showering in water that has been contaminated with MTBE.
- Receiving MTBE treatment for gallstones.

How can MTBE affect my health?

Breathing small amounts of MTBE for short periods may cause nose and throat irritation. Some people exposed to MTBE while pumping gasoline, driving their cars, or working

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

in gas stations have reported having headaches, nausea, dizziness, and mental confusion. However, the actual levels of exposure in these cases are unknown. In addition, these symptoms may have been caused by exposure to other chemicals.

There are no data on the effects in people of drinking MTBE. Studies with rats and mice suggest that drinking MTBE may cause gastrointestinal irritation, liver and kidney damage, and nervous system effects.

How likely is MTBE to cause cancer?

There is no evidence that MTBE causes cancer in humans. One study with rats found that breathing high levels of MTBE for long periods may cause kidney cancer. Another study with mice found that breathing high levels of MTBE for long periods may cause liver cancer.

The Department of Health and Human Services (DHHS), the International Agency for Research on Cancer (IARC), and the EPA have not classified MTBE as to its carcinogenicity.

Is there a medical test to show whether I've been exposed to MTBE?

MTBE and its breakdown product, butyl alcohol, can be detected in your breath, blood, or urine for up to 1 or 2 days after exposure. These tests aren't available at most doctors' offices, but can be done at special laboratories that have the right equipment. There is no other test specific to determining MTBE exposure.

Has the federal government made recommendations to protect human health?

The EPA has issued guidelines recommending that, to protect children, drinking water levels of MTBE not exceed 4 milligrams per liter of water (4 mg/L) for an exposure of 1-10 days, and 3 mg/L for longer-term exposures.

The American Conference of Governmental Industrial Hygienists (ACGIH) has recommended an exposure limit of 40 parts of MTBE per million parts of air (40 ppm) for an 8-hour workday, 40-hour workweek.

Glossary

Carcinogenicity: Ability to cause cancer.

CAS: Chemical Abstracts Service.

Evaporate: To change into a vapor or gas.

Milligram (mg): One thousandth of a gram.

ppm: Parts per million.

Sediment: Mud and debris that have settled to the bottom of a body of water.

This ToxFAQs information is taken from the 1996 Toxicological Profile for Methyl *tert*-Butyl Ether produced by the Agency for Toxic Substances and Disease Registry, Public Health Service, U.S. Department of Health and Human Services, Public Health Service in Atlanta, GA.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html> ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because these substances may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene happens mostly from breathing air contaminated from the burning of wood, tobacco, or fossil fuels, industrial discharges, or moth repellents. Exposure to large amounts of naphthalene may damage or destroy some of your red blood cells. Naphthalene has caused cancer in animals. Naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene have been found in at least 687, 36, and 412, respectively, of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What are naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

Naphthalene is a white solid that evaporates easily. Fuels such as petroleum and coal contain naphthalene. It is also called white tar, and tar camphor, and has been used in mothballs and moth flakes. Burning tobacco or wood produces naphthalene. It has a strong, but not unpleasant smell. The major commercial use of naphthalene is in the manufacture of polyvinyl chloride (PVC) plastics. Its major consumer use is in moth repellents and toilet deodorant blocks.

1-Methylnaphthalene and 2-methylnaphthalene are naphthalene-related compounds. 1-Methylnaphthalene is a clear liquid and 2-methylnaphthalene is a solid; both can be smelled in air and in water at very low concentrations.

1-Methylnaphthalene and 2-methylnaphthalene are used to make other chemicals such as dyes and resins. 2-Methylnaphthalene is also used to make vitamin K.

What happens to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene when they enter the environment?

- Naphthalene enters the environment from industrial and domestic sources, and from accidental spills.
- Naphthalene can dissolve in water to a limited degree and may be present in drinking water from wells close to hazardous waste sites and landfills.
- Naphthalene can become weakly attached to soil or pass through soil into underground water.
- In air, moisture and sunlight break it down within 1 day. In water, bacteria break it down or it evaporates into the air.
- Naphthalene does not accumulate in the flesh of animals or fish that you might eat.

1-Methylnaphthalene and 2-methylnaphthalene are expected to act like naphthalene in air, water, or soil because they have similar chemical and physical properties.

How might I be exposed to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

- Breathing low levels in outdoor air.
- Breathing air contaminated from industrial discharges or smoke from burning wood, tobacco, or fossil fuels.
- Using or making moth repellents, coal tar products, dyes or inks could expose you to these chemicals in the air.
- Drinking water from contaminated wells.
- Touching fabrics that are treated with moth repellents containing naphthalene.
- Exposure to naphthalene, 1-methylnaphthalene and 2-methylnaphthalene from eating foods or drinking beverages is unlikely.

How can naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene affect my health?

Exposure to large amounts of naphthalene may damage or destroy some of your red blood cells. This could cause you to have too few red blood cells until your body replaces the destroyed cells. This condition is called hemolytic anemia. Some symptoms of hemolytic anemia are fatigue, lack of appetite, restlessness, and pale skin. Exposure to large amounts of naphthalene may also cause nausea, vomiting, diarrhea, blood in the urine, and a yellow color to the skin. Animals sometimes develop cloudiness in their eyes after swallowing high amounts of naphthalene. It is not clear whether this also develops in people. Rats and mice that breathed naphthalene vapors daily for a lifetime developed irritation and inflammation of their nose and lungs. It is unclear if naphthalene

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

causes reproductive effects in animals; most evidence says it does not.

There are no studies of humans exposed to 1-methylnaphthalene or 2-methylnaphthalene.

Mice fed food containing 1-methylnaphthalene and 2-methylnaphthalene for most of their lives had part of their lungs filled with an abnormal material.

How likely are naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene to cause cancer?

There is no direct evidence in humans that naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene cause cancer.

However, cancer from naphthalene exposure has been seen in animal studies. Some female mice that breathed naphthalene vapors daily for a lifetime developed lung tumors. Some male and female rats exposed to naphthalene in a similar manner also developed nose tumors.

Based on the results from animal studies, the Department of Health and Human Services (DHHS) concluded that naphthalene is reasonably anticipated to be a human carcinogen. The International Agency for Research on Cancer (IARC) concluded that naphthalene is possibly carcinogenic to humans. The EPA determined that naphthalene is a possible human carcinogen (Group C) and that the data are inadequate to assess the human carcinogenic potential of 2-methylnaphthalene.

How can naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene affect children?

Hospitals have reported many cases of hemolytic anemia in children, including newborns and infants, who either ate naphthalene mothballs or deodorants cakes or who were in close contact with clothing or blankets stored in naphthalene mothballs. Naphthalene can move from a pregnant woman's blood to the unborn baby's blood. Naphthalene has been detected in some samples of breast milk from the general U.S. population, but not at levels that are expected to be of concern.

There is no information on whether naphthalene has affected development in humans. No developmental abnormalities were observed in the offspring from rats, mice, and rabbits fed naphthalene during pregnancy.

We do not have any information on possible health effects of 1-methylnaphthalene or 2-methylnaphthalene on children.

How can families reduce the risks of exposure to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

Families can reduce the risks of exposure to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene by avoiding smoking tobacco, generating smoke during cooking, or using

fireplaces or heating appliances in their homes.

If families use naphthalene-containing moth repellents, the material should be enclosed in containers that prevent vapors from escaping, and kept out of the reach from children.

Blankets and clothing stored with naphthalene moth repellents should be aired outdoors to remove naphthalene odors and washed before they are used.

Families should inform themselves of the contents of air deodorizers that are used in their homes and refrain from using deodorizers with naphthalene.

Is there a medical test to determine whether I've been exposed to naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene?

Tests are available that measure levels of these chemicals and their breakdown products in samples of urine, feces, blood, maternal milk, or body fat. These tests are not routinely available in a doctor's office because they require special equipment, but samples can be sent to special testing laboratories. These tests cannot determine exactly how much naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene you were exposed to or predict whether harmful effects will occur. If the samples are collected within a day or two of exposure, then the tests can show if you were exposed to a large or small amount of naphthalene, 1-methylnaphthalene, or 2-methylnaphthalene.

Has the federal government made recommendations to protect human health?

The EPA recommends that children not drink water with over 0.5 parts per million (0.5 ppm) naphthalene for more than 10 days or over 0.4 ppm for any longer than 7 years. Adults should not drink water with more than 1 ppm for more than 7 years. For water consumed over a lifetime (70 years), the EPA suggests that it contain no more than 0.1 ppm naphthalene.

The Occupational Safety and Health Administration (OSHA) set a limit of 10 ppm for the level of naphthalene in workplace air during an 8-hour workday, 40-hour workweek. The National Institute for Occupational Safety and Health (NIOSH) considers more than 500 ppm of naphthalene in air to be immediately dangerous to life or health. This is the exposure level of a chemical that is likely to impair a worker's ability to leave a contaminate area and therefore, results in permanent health problems or death.

You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet was created from information presented in the Agency for Toxic Substances and Disease Registry (ATSDR) Case Studies in Environmental Medicine Course (ATSDR, 2007). This fact sheet answers the most frequently asked health questions (FAQs) about nitrate and nitrite. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

Highlights: The widespread use of nitrate fertilizers has increased the risk of well water contamination in rural areas. Shallow, rural domestic wells are those most likely to be contaminated with nitrates, especially in agricultural areas where nitrogen based fertilizers are in use. Other nitrate sources in well water include seepage from septic sewer systems, or other contaminants. The conversion of nitrates to nitrites in the body significantly enhances nitrates' toxicity. Infants younger than four months are at particular risk of nitrate toxicity from contaminated well water. Parents that use water to make formula for infants should be especially careful.

What are nitrates and nitrites?

Nitrate (NO_3^-) and nitrite (NO_2^-) are naturally occurring inorganic ions that are part of the nitrogen cycle. Microbial action in soil or water decomposes wastes containing organic nitrogen into ammonia, which is then oxidized to nitrite and nitrate.

Because nitrite is easily oxidized to nitrate, nitrate is the compound predominantly found in groundwater and surface water.

Contamination with nitrogen-containing fertilizers (e.g. potassium nitrate and ammonium nitrate), or animal or human organic wastes, can raise the concentration of nitrate in water.

What happens to nitrate/nitrite when it enters the environment?

- Nitrate-containing compounds in the soil are generally soluble and readily migrate with groundwater.
- Microbial action in soil or water decomposes wastes containing organic nitrogen into ammonia, which is then oxidized to nitrite and nitrate.

How might I be exposed to nitrate/nitrite?

- Ingesting nitrate and nitrite in well water used for drinking water
- Infants ingesting formula made with water containing nitrate or nitrite.

- Ingesting contaminated foodstuffs
- Ingesting prepared baby foods and sausage preserved with nitrates and nitrites.
- Ingesting certain medications and breathing volatile nitrite inhalants.

How can nitrate/nitrite affect my health?

Ingesting high levels of nitrate/nitrite can cause methemoglobinemia. Methemoglobinemia is a disorder characterized by the presence of a higher than normal level of methemoglobin in the blood. Methemoglobin is a form of hemoglobin that does not bind oxygen. When its concentration is elevated in red blood cells, anemia and tissue hypoxia can occur.

How likely is nitrate/nitrite to cause cancer?

Nitrate and nitrite have not undergone an evaluation of carcinogenic potential by the U.S. Environmental Protection Agency (USEPA).

How can nitrate/nitrite affect children?

As with adults, ingesting high levels of nitrate/nitrite can cause methemoglobinemia. Infants under the age of four months are at higher risk due to their reduced ability to convert methemoglobin back to hemoglobin. In addition, the high pH of the infant gastrointestinal system favors the growth of bacteria that reduce nitrate to nitrite, which is responsible for creation of methemoglobin.

How can families reduce the risks of exposure to nitrate/nitrite?

- Well water should be periodically tested for nitrate/nitrite.
- If your drinking water has elevated levels of nitrate/nitrate you should use cleaner sources of water.
- If your drinking water has elevated levels of nitrate/nitrate you should not use it to make baby formula.

Is there a medical test to determine whether I've been exposed to nitrate/nitrite?

The most useful diagnostic tests measure the methemoglobin concentration in blood, which is an indicator of nitrate/nitrite toxicity. Tests include both a visual observation of blood, which is chocolate-brown in appearance when there is a high

concentration of methemoglobin, and measurement of the oxygen carrying capacity of blood, which is reduced when a high level of methemoglobin is present.

Has the federal government made recommendations to protect human health?

The USEPA has set an enforceable standard called a maximum contaminant level (MCL) for nitrates at 10 parts per million (ppm), and for nitrites at 1 ppm. The USEPA believes that exposure below this level is not expected to cause health problems.

The Joint Expert Committee on Food Additives (JECFA) of the Food and Agriculture Organization of the United Nations/World Health Organization and the European Commission's Scientific Committee on Food have set an acceptable daily intake (ADI) for nitrate of 0 – 3.7 mg nitrate ion/kg body weight.

You can also contact your community or state health or environmental quality department if you have any questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about tetrachloroethylene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Tetrachloroethylene is a manufactured chemical used for dry cleaning and metal degreasing. Exposure to very high concentrations of tetrachloroethylene can cause dizziness, headaches, sleepiness, confusion, nausea, difficulty in speaking and walking, unconsciousness, and death. Tetrachloroethylene has been found in at least 771 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is tetrachloroethylene?

(Pronounced tět'rə-klôr' 0-ěth'ə-lēn')

Tetrachloroethylene is a manufactured chemical that is widely used for dry cleaning of fabrics and for metal-degreasing. It is also used to make other chemicals and is used in some consumer products.

Other names for tetrachloroethylene include perchloroethylene, PCE, and tetrachloroethene. It is a nonflammable liquid at room temperature. It evaporates easily into the air and has a sharp, sweet odor. Most people can smell tetrachloroethylene when it is present in the air at a level of 1 part tetrachloroethylene per million parts of air (1 ppm) or more, although some can smell it at even lower levels.

What happens to tetrachloroethylene when it enters the environment?

- Much of the tetrachloroethylene that gets into water or soil evaporates into the air.
- Microorganisms can break down some of the tetrachloroethylene in soil or underground water.
- In the air, it is broken down by sunlight into other chemicals or brought back to the soil and water by rain.
- It does not appear to collect in fish or other animals that live in water.

How might I be exposed to tetrachloroethylene?

- When you bring clothes from the dry cleaners, they will release small amounts of tetrachloroethylene into the air.
- When you drink water containing tetrachloroethylene, you are exposed to it.

How can tetrachloroethylene affect my health?

High concentrations of tetrachloroethylene (particularly in closed, poorly ventilated areas) can cause dizziness, headache, sleepiness, confusion, nausea, difficulty in speaking and walking, unconsciousness, and death.

Irritation may result from repeated or extended skin contact with it. These symptoms occur almost entirely in work (or hobby) environments when people have been accidentally exposed to high concentrations or have intentionally used tetrachloroethylene to get a "high."

In industry, most workers are exposed to levels lower than those causing obvious nervous system effects. The health effects of breathing in air or drinking water with low levels of tetrachloroethylene are not known.

Results from some studies suggest that women who work in dry cleaning industries where exposures to tetrachloroethyl-

ToxFAQs Internet home page via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

ene can be quite high may have more menstrual problems and spontaneous abortions than women who are not exposed. However, it is not known if tetrachloroethylene was responsible for these problems because other possible causes were not considered.

Results of animal studies, conducted with amounts much higher than those that most people are exposed to, show that tetrachloroethylene can cause liver and kidney damage. Exposure to very high levels of tetrachloroethylene can be toxic to the unborn pups of pregnant rats and mice. Changes in behavior were observed in the offspring of rats that breathed high levels of the chemical while they were pregnant.

How likely is tetrachloroethylene to cause cancer?

The Department of Health and Human Services (DHHS) has determined that tetrachloroethylene may reasonably be anticipated to be a carcinogen. Tetrachloroethylene has been shown to cause liver tumors in mice and kidney tumors in male rats.

Is there a medical test to show whether I've been exposed to tetrachloroethylene?

One way of testing for tetrachloroethylene exposure is to measure the amount of the chemical in the breath, much the same way breath-alcohol measurements are used to determine the amount of alcohol in the blood.

Because it is stored in the body's fat and slowly released into the bloodstream, tetrachloroethylene can be detected in the breath for weeks following a heavy exposure.

Tetrachloroethylene and trichloroacetic acid (TCA), a breakdown product of tetrachloroethylene, can be detected in the blood. These tests are relatively simple to perform. These tests aren't available at most doctors' offices, but can be per-

formed at special laboratories that have the right equipment.

Because exposure to other chemicals can produce the same breakdown products in the urine and blood, the tests for breakdown products cannot determine if you have been exposed to tetrachloroethylene or the other chemicals.

Has the federal government made recommendations to protect human health?

The EPA maximum contaminant level for the amount of tetrachloroethylene that can be in drinking water is 0.005 milligrams tetrachloroethylene per liter of water (0.005 mg/L).

The Occupational Safety and Health Administration (OSHA) has set a limit of 100 ppm for an 8-hour workday over a 40-hour workweek.

The National Institute for Occupational Safety and Health (NIOSH) recommends that tetrachloroethylene be handled as a potential carcinogen and recommends that levels in workplace air should be as low as possible.

Glossary

Carcinogen: A substance with the ability to cause cancer.

CAS: Chemical Abstracts Service.

Milligram (mg): One thousandth of a gram.

Nonflammable: Will not burn.

This fact sheet answers the most frequently asked health questions (FAQs) about thallium. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to thallium occurs mainly from eating food. Exposure to higher levels of thallium may occur in the workplace. Breathing high levels of thallium may result in effects on the nervous system, while ingesting high levels of it results in vomiting, diarrhea, temporary hair loss, and other effects. This chemical has been found in at least 210 of 1,416 National Priorities List sites identified by the Environmental Protection Agency.

What is thallium?

(Pronounced thăll/ĕ-əm)

Pure thallium is a bluish-white metal that is found in trace amounts in the earth's crust. In the past, thallium was obtained as a by-product from smelting other metals; however, it has not been produced in the United States since 1984.

Currently, all the thallium is obtained from imports and from thallium reserves.

In its pure form, thallium is odorless and tasteless. It can also be found combined with other substances such as bromine, chlorine, fluorine, and iodine. When it's combined, it appears colorless-to-white or yellow.

Thallium is used mostly in manufacturing electronic devices, switches, and closures, primarily for the semiconductor industry. It also has limited use in the manufacture of special glass and for certain medical procedures.

What happens to thallium when it enters the environment?

- Thallium enters the environment primarily from coal-burning and smelting, in which it is a trace contaminant of the raw materials.
- It stays in the air, water, and soil for a long time and is not broken down.

- Some thallium compounds are removed from the atmosphere in rain and snow.
- It's absorbed by plants and enters the food chain.
- It builds up in fish and shellfish.

How might I be exposed to thallium?

- Eating food contaminated with thallium may be a major source of exposure for most people.
- Breathing workplace air in industries that use thallium
- Smoking cigarettes.
- Living near hazardous waste sites containing thallium (may result in higher than normal exposures).
- Touching or, for children, eating soil contaminated with thallium.
- Breathing low levels in air and water.

How can thallium affect my health?

Exposure to high levels of thallium can result in harmful health effects. A study on workers exposed on the job over several years reported nervous system effects, such as numbness of fingers and toes, from breathing thallium.

Studies in people who ingested large amounts of thallium over a short time have reported vomiting, diarrhea, temporary hair loss, and effects on the nervous system, lungs, heart, liver,

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

and kidneys. It has caused death. It is not known what the effects are from ingesting low levels of thallium over a long time.

Birth defects were not reported in the children of mothers exposed to low levels from eating vegetables and fruits contaminated with thallium. Studies in rats, however, exposed to high levels of thallium, showed adverse developmental effects.

It is not known if breathing or ingesting thallium affects human reproduction. Studies showed that rats that ingested thallium for several weeks had some adverse reproductive effects. Animal data suggest that the male reproductive system may be susceptible to damage by low levels of thallium.

There is no information available on the health effects of skin contact with thallium in people or animals.

How likely is thallium to cause cancer?

The Department of Health and Human Services, the International Agency for Research on Cancer, and the Environmental Protection Agency (EPA) have not classified thallium as to its human carcinogenicity.

No studies are available in people or animals on the carcinogenic effects of breathing, ingesting, or touching thallium.

Is there a medical test to show whether I've been exposed to thallium?

There are medical tests available to measure levels of thallium in urine and hair. In addition, thallium can also be measured in blood; however, this is not a good indicator of exposure since thallium only stays in blood a very short time.

These tests require special equipment that is not usually available in most doctor's offices. In addition, these tests cannot determine if adverse health effects will occur from the exposure to thallium.

Has the federal government made recommendations to protect human health?

The EPA requires that discharges or accidental spills into the environment of 1,000 pounds or more of thallium be reported.

The Occupational Safety and Health Administration (OSHA) has set an exposure limit of 0.1 milligrams per cubic meter (0.1 mg/m³) for thallium in workplace air. The American Conference of Governmental Industrial Hygienists (ACGIH) has established the same guidelines as OSHA for the workplace.

The National Institute for Occupational Safety and Health (NIOSH) has recommended that 15 mg/m³ of thallium be considered immediately dangerous to life and health. This is the exposure level of a chemical that is likely to cause permanent health problems or death.

Glossary

Carcinogenicity: Ability to cause cancer.

Ingesting: Taking food or drink into your body.

Milligram (mg): One thousandth of a gram.

This fact sheet answers the most frequently asked health questions (FAQs) about polycyclic aromatic hydrocarbons (PAHs). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

SUMMARY: Exposure to polycyclic aromatic hydrocarbons usually occurs by breathing air contaminated by wild fires or coal tar, or by eating foods that have been grilled. PAHs have been found in at least 600 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What are polycyclic aromatic hydrocarbons?

(Pronounced pŏl'ī-sī'klīk ār'ə-măt'īk hī'drə-kar'bənz)

Polycyclic aromatic hydrocarbons (PAHs) are a group of over 100 different chemicals that are formed during the incomplete burning of coal, oil and gas, garbage, or other organic substances like tobacco or charbroiled meat. PAHs are usually found as a mixture containing two or more of these compounds, such as soot.

Some PAHs are manufactured. These pure PAHs usually exist as colorless, white, or pale yellow-green solids. PAHs are found in coal tar, crude oil, creosote, and roofing tar, but a few are used in medicines or to make dyes, plastics, and pesticides.

What happens to PAHs when they enter the environment?

- PAHs enter the air mostly as releases from volcanoes, forest fires, burning coal, and automobile exhaust.
- PAHs can occur in air attached to dust particles.
- Some PAH particles can readily evaporate into the air from soil or surface waters.
- PAHs can break down by reacting with sunlight and other chemicals in the air, over a period of days to weeks.

- PAHs enter water through discharges from industrial and wastewater treatment plants.
- Most PAHs do not dissolve easily in water. They stick to solid particles and settle to the bottoms of lakes or rivers.
- Microorganisms can break down PAHs in soil or water after a period of weeks to months.
- In soils, PAHs are most likely to stick tightly to particles; certain PAHs move through soil to contaminate underground water.
- PAH contents of plants and animals may be much higher than PAH contents of soil or water in which they live.

How might I be exposed to PAHs?

- Breathing air containing PAHs in the workplace of coking, coal-tar, and asphalt production plants; smoke-houses; and municipal trash incineration facilities.
- Breathing air containing PAHs from cigarette smoke, wood smoke, vehicle exhausts, asphalt roads, or agricultural burn smoke.
- Coming in contact with air, water, or soil near hazardous waste sites.
- Eating grilled or charred meats; contaminated cereals, flour, bread, vegetables, fruits, meats; and processed or pickled foods.
- Drinking contaminated water or cow's milk.

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

- ❑ Nursing infants of mothers living near hazardous waste sites may be exposed to PAHs through their mother's milk.

How can PAHs affect my health?

Mice that were fed high levels of one PAH during pregnancy had difficulty reproducing and so did their offspring. These offspring also had higher rates of birth defects and lower body weights. It is not known whether these effects occur in people.

Animal studies have also shown that PAHs can cause harmful effects on the skin, body fluids, and ability to fight disease after both short- and long-term exposure. But these effects have not been seen in people.

How likely are PAHs to cause cancer?

The Department of Health and Human Services (DHHS) has determined that some PAHs may reasonably be expected to be carcinogens.

Some people who have breathed or touched mixtures of PAHs and other chemicals for long periods of time have developed cancer. Some PAHs have caused cancer in laboratory animals when they breathed air containing them (lung cancer), ingested them in food (stomach cancer), or had them applied to their skin (skin cancer).

Is there a medical test to show whether I've been exposed to PAHs?

In the body, PAHs are changed into chemicals that can attach to substances within the body. There are special tests that can detect PAHs attached to these substances in body tissues or blood. However, these tests cannot tell whether any

health effects will occur or find out the extent or source of your exposure to the PAHs. The tests aren't usually available in your doctor's office because special equipment is needed to conduct them.

Has the federal government made recommendations to protect human health?

The Occupational Safety and Health Administration (OSHA) has set a limit of 0.2 milligrams of PAHs per cubic meter of air (0.2 mg/m^3). The OSHA Permissible Exposure Limit (PEL) for mineral oil mist that contains PAHs is 5 mg/m^3 averaged over an 8-hour exposure period.

The National Institute for Occupational Safety and Health (NIOSH) recommends that the average workplace air levels for coal tar products not exceed 0.1 mg/m^3 for a 10-hour workday, within a 40-hour workweek. There are other limits for workplace exposure for things that contain PAHs, such as coal, coal tar, and mineral oil.

Glossary

Carcinogen: A substance that can cause cancer.

Ingest: Take food or drink into your body.

Agency for Toxic Substances and Disease Registry (ATSDR). 1995. Toxicological profile for polycyclic aromatic hydrocarbons. Atlanta, GA: U.S. Department of Health and Human Services, Public Health Service.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-888-422-8737, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html> ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about chlorinated dibenzo-p-dioxins (CDDs). For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to chlorinated dibenzo-p-dioxins (CDDs) (75 chemicals) occurs mainly from eating food that contains the chemicals. One chemical in this group, 2,3,7,8-tetrachlorodibenzo-p-dioxin or 2,3,7,8-TCDD, has been shown to be very toxic in animal studies. It causes effects on the skin and may cause cancer in people. This chemical has been found in at least 91 of 1,467 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What are CDDs?

CDDs are a family of 75 chemically related compounds commonly known as chlorinated dioxins. One of these compounds is called 2,3,7,8-TCDD. It is one of the most toxic of the CDDs and is the one most studied.

In the pure form, CDDs are crystals or colorless solids. CDDs enter the environment as mixtures containing a number of individual components. 2,3,7,8-TCDD is odorless and the odors of the other CDDs are not known.

CDDs are not intentionally manufactured by industry except for research purposes. They (mainly 2,3,7,8-TCDD) may be formed during the chlorine bleaching process at pulp and paper mills. CDDs are also formed during chlorination by waste and drinking water treatment plants. They can occur as contaminants in the manufacture of certain organic chemicals. CDDs are released into the air in emissions from municipal solid waste and industrial incinerators.

What happens to CDDs when they enter the environment?

- When released into the air, some CDDs may be transported long distances, even around the globe.

- When released in waste waters, some CDDs are broken down by sunlight, some evaporate to air, but most attach to soil and settle to the bottom sediment in water.
- CDD concentrations may build up in the food chain, resulting in measurable levels in animals.

How might I be exposed to CDDs?

- Eating food, primarily meat, dairy products, and fish, makes up more than 90% of the intake of CDDs for the general population.
- Breathing low levels in air and drinking low levels in water.
- Skin contact with certain pesticides and herbicides.
- Living near an uncontrolled hazardous waste site containing CDDs or incinerators releasing CDDs.
- Working in industries involved in producing certain pesticides containing CDDs as impurities, working at paper and pulp mills, or operating incinerators.

How can CDDs affect my health?

The most noted health effect in people exposed to large amounts of 2,3,7,8-TCDD is chloracne. Chloracne is a severe skin disease with acne-like lesions that occur mainly on the face and upper body. Other skin effects noted in people exposed to high doses of 2,3,7,8-TCDD include skin rashes, dis-

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

coloration, and excessive body hair. Changes in blood and urine that may indicate liver damage also are seen in people. Exposure to high concentrations of CDDs may induce long-term alterations in glucose metabolism and subtle changes in hormonal levels.

In certain animal species, 2,3,7,8-TCDD is especially harmful and can cause death after a single exposure. Exposure to lower levels can cause a variety of effects in animals, such as weight loss, liver damage, and disruption of the endocrine system. In many species of animals, 2,3,7,8-TCDD weakens the immune system and causes a decrease in the system's ability to fight bacteria and viruses. In other animal studies, exposure to 2,3,7,8-TCDD has caused reproductive damage and birth defects. Some animal species exposed to CDDs during pregnancy had miscarriages and the offspring of animals exposed to 2,3,7,8-TCDD during pregnancy often had severe birth defects including skeletal deformities, kidney defects, and weakened immune responses.

How likely are CDDs to cause cancer?

Several studies suggest that exposure to 2,3,7,8-TCDD increases the risk of several types of cancer in people. Animal studies have also shown an increased risk of cancer from exposure to 2,3,7,8-TCDD.

The World Health Organization (WHO) has determined that 2,3,7,8-TCDD is a human carcinogen.

The Department of Health and Human Services (DHHS) has determined that 2,3,7,8-TCDD may reasonably be anticipated to cause cancer.

How can CDDs affect children?

Very few studies have looked at the effects of CDDs on children. Chloracne has been seen in children exposed to high levels of CDDs. We don't know if CDDs affect the ability of people to have children or if it causes birth defects, but given the effects observed in animal studies, this cannot be ruled out.

How can families reduce the risk of exposure to CDDs?

- Children should avoid playing in soils near uncontrolled hazardous waste sites.
- Discourage children from eating dirt or putting toys or other objects in their mouths.
- Everyone should wash hands frequently if playing or working near uncontrolled hazardous waste sites.
- For new mothers and young children, restrict eating foods from the proximity of uncontrolled sites with known CDDs.

Is there a medical test to show whether I've been exposed to CDDs?

Tests are available to measure CDD levels in body fat, blood, and breast milk, but these tests are not routinely available. Most people have low levels of CDDs in their body fat and blood, and levels considerably above these levels indicate past exposure to above-normal levels of 2,3,7,8-TCDD. Although CDDs stay in body fat for a long time, tests cannot be used to determine when exposure occurred.

Has the federal government made recommendations to protect human health?

The EPA has set a limit of 0.00003 micrograms of 2,3,7,8-TCDD per liter of drinking water (0.00003 µg/L). Discharges, spills, or accidental releases of 1 pound or more of 2,3,7,8-TCDD must be reported to EPA. The Food and Drug Administration (FDA) recommends against eating fish and shellfish with levels of 2,3,7,8-TCDD greater than 50 parts per trillion (50 ppt).

This fact sheet answers the most frequently asked health questions (FAQs) about trichloroethylene. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. This information is important because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Trichloroethylene is a colorless liquid which is used as a solvent for cleaning metal parts. Drinking or breathing high levels of trichloroethylene may cause nervous system effects, liver and lung damage, abnormal heartbeat, coma, and possibly death. Trichloroethylene has been found in at least 852 of the 1,430 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is trichloroethylene?

Trichloroethylene (TCE) is a nonflammable, colorless liquid with a somewhat sweet odor and a sweet, burning taste. It is used mainly as a solvent to remove grease from metal parts, but it is also an ingredient in adhesives, paint removers, typewriter correction fluids, and spot removers.

Trichloroethylene is not thought to occur naturally in the environment. However, it has been found in underground water sources and many surface waters as a result of the manufacture, use, and disposal of the chemical.

What happens to trichloroethylene when it enters the environment?

- ❑ Trichloroethylene dissolves a little in water, but it can remain in ground water for a long time.
- ❑ Trichloroethylene quickly evaporates from surface water, so it is commonly found as a vapor in the air.
- ❑ Trichloroethylene evaporates less easily from the soil than from surface water. It may stick to particles and remain for a long time.
- ❑ Trichloroethylene may stick to particles in water, which will cause it to eventually settle to the bottom sediment.
- ❑ Trichloroethylene does not build up significantly in

plants and animals.

How might I be exposed to trichloroethylene?

- ❑ Breathing air in and around the home which has been contaminated with trichloroethylene vapors from shower water or household products such as spot removers and typewriter correction fluid.
- ❑ Drinking, swimming, or showering in water that has been contaminated with trichloroethylene.
- ❑ Contact with soil contaminated with trichloroethylene, such as near a hazardous waste site.
- ❑ Contact with the skin or breathing contaminated air while manufacturing trichloroethylene or using it at work to wash paint or grease from skin or equipment.

How can trichloroethylene affect my health?

Breathing small amounts may cause headaches, lung irritation, dizziness, poor coordination, and difficulty concentrating.

Breathing large amounts of trichloroethylene may cause impaired heart function, unconsciousness, and death. Breathing it for long periods may cause nerve, kidney, and liver damage.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Drinking large amounts of trichloroethylene may cause nausea, liver damage, unconsciousness, impaired heart function, or death.

Drinking small amounts of trichloroethylene for long periods may cause liver and kidney damage, impaired immune system function, and impaired fetal development in pregnant women, although the extent of some of these effects is not yet clear.

Skin contact with trichloroethylene for short periods may cause skin rashes.

How likely is trichloroethylene to cause cancer?

Some studies with mice and rats have suggested that high levels of trichloroethylene may cause liver, kidney, or lung cancer. Some studies of people exposed over long periods to high levels of trichloroethylene in drinking water or in workplace air have found evidence of increased cancer. Although, there are some concerns about the studies of people who were exposed to trichloroethylene, some of the effects found in people were similar to effects in animals.

In its 9th Report on Carcinogens, the National Toxicology Program (NTP) determined that trichloroethylene is “reasonably anticipated to be a human carcinogen.” The International Agency for Research on Cancer (IARC) has determined that trichloroethylene is “probably carcinogenic to humans.”

Is there a medical test to show whether I've been exposed to trichloroethylene?

If you have recently been exposed to trichloroethylene, it can be detected in your breath, blood, or urine. The breath test, if it is performed soon after exposure, can tell if you have been exposed to even a small amount of trichloroethylene.

Exposure to larger amounts is assessed by blood

and urine tests, which can detect trichloroethylene and many of its breakdown products for up to a week after exposure. However, exposure to other similar chemicals can produce the same breakdown products, so their detection is not absolute proof of exposure to trichloroethylene. This test isn't available at most doctors' offices, but can be done at special laboratories that have the right equipment.

Has the federal government made recommendations to protect human health?

The EPA has set a maximum contaminant level for trichloroethylene in drinking water at 0.005 milligrams per liter (0.005 mg/L) or 5 parts of TCE per billion parts water.

The EPA has also developed regulations for the handling and disposal of trichloroethylene.

The Occupational Safety and Health Administration (OSHA) has set an exposure limit of 100 parts of trichloroethylene per million parts of air (100 ppm) for an 8-hour workday, 40-hour workweek.

Glossary

Carcinogenicity: The ability of a substance to cause cancer.

CAS: Chemical Abstracts Service.

Evaporate: To change into a vapor or gas.

Milligram (mg): One thousandth of a gram.

Nonflammable: Will not burn.

ppm: Parts per million.

Sediment: Mud and debris that have settled to the bottom of a body of water.

Solvent: A chemical that dissolves other substances.

This fact sheet answers the most frequently asked health questions (FAQs) about uranium. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It's important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Uranium is a naturally occurring chemical substance that is mildly radioactive. Everyone is exposed to low amounts of uranium through food, air, and water. Exposure to high levels of uranium can cause kidney disease. It is not known to cause cancer, but can decay into other radioactive materials that may. Uranium above background levels has been found in at least 54 of the 1,517 National Priorities List sites identified by the Environmental Protection Agency (EPA).

What is uranium?

(Pronounced yoo-rā'nē-əm)

Uranium is a common naturally occurring and radioactive substance. It is a normal part of rocks, soil, air, and water, and it occurs in nature in the form of minerals - but never as a metal. Uranium metal is silver-colored with a gray surface and is nearly as strong as steel. Natural uranium is a mixture of three types or isotopes called U-234 (^{234}U), U-235 (^{235}U), and U-238 (^{238}U). All three are the same chemical, but they have different radioactive properties.

Typical concentrations in soil are a few parts per million (ppm). Some rocks contain high enough mineral concentrations of uranium to be mined. The rocks are taken to a chemical plant where the uranium is taken out and made into uranium chemicals or metal. The remaining sand is called mill tailings. Tailings are rich in the chemicals and radioactive materials that were not removed, such as radium and thorium.

One of the radioactive properties of uranium is half-life, or the time it takes for half of the isotope to give off its radiation and change into another substance. The half-lives are very long (around 200,000 years for ^{234}U , 700 million years for ^{235}U , and 5 billion years for ^{238}U). This is why uranium still exists in nature and has not all decayed away.

The isotope ^{235}U is useful as a fuel in power plants and weapons. To make fuel, natural uranium is separated into two portions. The fuel portion has more ^{235}U than normal and is called enriched uranium. The leftover portion with less ^{235}U than normal is called depleted uranium, or DU. Natural, de-

pleted, and enriched uranium are chemically identical. DU is the least radioactive and enriched uranium is the most.

What happens to uranium when it enters the environment?

- Uranium is already naturally present throughout the environment. Human activities, wind, streams, and volcanoes can move the uranium around and change the levels that you are exposed to.
- Uranium is found in soil where it may stay for billions of years.
- It exists as dust in the air and the dust settles onto surface water, soil, and plants.
- Uranium enters water by dissolving soil, eroding soil and rocks, or in releases from processing plants. Larger particles settle into the bottom of lakes, rivers, and ponds and join uranium that is there naturally.
- Some plants may absorb uranium or it may stick to the root surface.

How might I be exposed to uranium?

- Breathing air or drinking water in a place that has higher than background levels of uranium.
- Eating food grown in areas with higher than background levels of uranium.
- Working in factories that process uranium or with phosphate fertilizers, or living near any type of mine.
- Living near a coal-fired power plant.

How can uranium affect my health?

All uranium mixtures (natural, depleted, and enriched) have the same chemical effect on your body. Large amounts of uranium can react with the tissues in your body and damage

ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>

your kidneys. The radiation damage from exposure to high levels of natural or depleted uranium are not known to cause cancer (see next section).

How likely is uranium to cause cancer?

Humans and animals exposed to high levels of uranium did not have higher cancer rates. The Committee on the Biological Effects of Ionizing Radiation (BEIR IV) reported that eating food or drinking water that has normal amounts of uranium will most likely not cause cancer.

Uranium can decay into other radioactive substances, such as radium, which can cause cancer if you are exposed to enough of them for a long enough period of time. Studies have reported lung and other cancers in uranium miners; however, the miners also smoked and were exposed to other substances that cause cancer, such as radon and silica dust.

How can uranium affect children?

Like adults, children are exposed to small amounts of uranium in air, food, and drinking water. If children were exposed to very large amounts of uranium, it is possible that they might have kidney damage like that seen in adults. We do not know whether children differ from adults in their susceptibility to the health effects of uranium exposure.

It is not known if exposure to uranium can affect the developing human fetus. In laboratory animals, high doses of uranium in drinking water resulted in birth defects and an increase in fetal deaths. Measurements of uranium have not been made in pregnant women, so we do not know if uranium can cross the placenta and enter the fetus. In an experiment with pregnant animals, only a small amount of the injected uranium reached the fetus.

How can families reduce the risk of exposure to uranium?

If your doctor finds that you have been exposed to significant amounts of uranium, ask whether your children might also be exposed. Your doctor might need to ask your state health department to investigate.

It is possible that higher-than-normal levels of uranium may be in the soil at a hazardous waste site. If you live near such a hazardous waste site, you should prevent your children from eating dirt and make sure that they wash their hands frequently and before eating. You should also wash fruits and vegetables grown in that soil well, and consider discarding the outside portion of root vegetables.

Is there a medical test to show whether I've been exposed to uranium?

Uranium is in your normal diet, so there will always be some level of uranium in all parts of your body. Uranium is normally measured in a sample of urine collected and sent to a laboratory. Blood, feces, and tissue samples are rarely used. Because most uranium leaves the body within a few days, higher than normal amounts in your urine shows whether you have been exposed to larger-than-normal amounts within the last week or so. Some highly sensitive radiation methods can measure uranium levels for a long time after you take in a large amount. Also, some radiation equipment can tell if uranium is on your skin.

Has the federal government made recommendations to protect human health?

The EPA requires that spills or accidental releases of uranium waste into the environment containing 0.1 curies or more of radioactivity must be reported to the EPA.

The EPA is currently working to develop an appropriate drinking water limit for uranium based on a broad range of human and animal health studies.

The Occupational Safety and Health Administration has set occupational exposure limits for uranium in breathing air over an 8-hour workday, 40-hour workweek. The limits are 0.05 milligrams per cubic meter (0.05 mg/m³) for soluble uranium dust and 0.25 mg/m³ for insoluble uranium dust.

This fact sheet answers the most frequently asked health questions (FAQs) about vinyl chloride. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to vinyl chloride occurs mainly in the workplace. Breathing high levels of vinyl chloride for short periods of time can cause dizziness, sleepiness, unconsciousness, and at extremely high levels can cause death. Breathing vinyl chloride for long periods of time can result in permanent liver damage, immune reactions, nerve damage, and liver cancer. This substance has been found in at least 616 of the 1,662 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is vinyl chloride?

Vinyl chloride is a colorless gas. It burns easily and it is not stable at high temperatures. It has a mild, sweet odor. It is a manufactured substance that does not occur naturally. It can be formed when other substances such as trichloroethane, trichloroethylene, and tetrachloroethylene are broken down. Vinyl chloride is used to make polyvinyl chloride (PVC). PVC is used to make a variety of plastic products, including pipes, wire and cable coatings, and packaging materials.

Vinyl chloride is also known as chloroethene, chloroethylene, and ethylene monochloride.

What happens to vinyl chloride when it enters the environment?

- Liquid vinyl chloride evaporates easily. Vinyl chloride in water or soil evaporates rapidly if it is near the surface.
- Vinyl chloride in the air breaks down in a few days to other substances, some of which can be harmful.
- Small amounts of vinyl chloride can dissolve in water.
- Vinyl chloride is unlikely to build up in plants or animals that you might eat.

How might I be exposed to vinyl chloride?

- Breathing vinyl chloride that has been released from plastics industries, hazardous waste sites, and landfills.
- Breathing vinyl chloride in air or during contact with your skin or eyes in the workplace.
- Drinking water from contaminated wells.

How can vinyl chloride affect my health?

Breathing high levels of vinyl chloride can cause you to feel dizzy or sleepy. Breathing very high levels can cause you to pass out, and breathing extremely high levels can cause death.

Some people who have breathed vinyl chloride for several years have changes in the structure of their livers. People are more likely to develop these changes if they breathe high levels of vinyl chloride. Some people who work with vinyl chloride have nerve damage and develop immune reactions. The lowest levels that produce liver changes, nerve damage, and immune reaction in people are not known. Some workers exposed to very high levels of vinyl chloride have problems with the blood flow in their hands. Their fingers turn white and hurt when they go into the cold.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

The effects of drinking high levels of vinyl chloride are unknown. If you spill vinyl chloride on your skin, it will cause numbness, redness, and blisters.

Animal studies have shown that long-term exposure to vinyl chloride can damage the sperm and testes.

How likely is vinyl chloride to cause cancer?

The U.S. Department of Health and Human Services has determined that vinyl chloride is a known carcinogen. Studies in workers who have breathed vinyl chloride over many years showed an increased risk of liver, brain, lung cancer, and some cancers of the blood have also been observed in workers.

How can vinyl chloride affect children?

It has not been proven that vinyl chloride causes birth defects in humans, but studies in animals suggest that vinyl chloride might affect growth and development. Animal studies also suggest that infants and young children might be more susceptible than adults to vinyl chloride-induced cancer.

How can families reduce the risk of exposure to vinyl chloride?

Tobacco smoke contains low levels of vinyl chloride, so limiting your family's exposure to cigarette or cigar smoke may help reduce their exposure to vinyl chloride.

Is there a medical test to show whether I've been exposed to vinyl chloride?

The results of several tests can sometimes show if you have been exposed to vinyl chloride. Vinyl chloride can be measured in your breath, but the test must be done shortly after exposure. This is not helpful for measuring very low levels of vinyl chloride.

The amount of the major breakdown product of vinyl chloride, thiodiglycolic acid, in the urine may give some information about exposure. However, this test must be done shortly after exposure and does not reliably indicate the level of exposure.

Has the federal government made recommendations to protect human health?

Vinyl chloride is regulated in drinking water, food, and air. The EPA requires that the amount of vinyl chloride in drinking water not exceed 0.002 milligrams per liter (mg/L) of water.

The Occupational Safety and Health Administration (OSHA) has set a limit of 1 part vinyl chloride per 1 million parts of air (1 ppm) in the workplace.

The Food and Drug Administration (FDA) regulates the vinyl chloride content of various plastics. These include plastics that carry liquids and plastics that contact food. The limits for vinyl chloride content vary depending on the nature of the plastic and its use.
