PREFACE

The Final Report for the Public Health Evaluation (PHE) is comprised of three (3) volumes, each with a specific purpose:

Naples Public Health Evaluation: Phase II Environmental Testing Support Assessment, Public Health Evaluation, Volume I, Naval Support Activity Naples, Italy (Tetra Tech, 2010) – this report presents the results of the soil, soil gas, water, and ambient air samples collected for the Phase II investigation of the Naples PHE. This report also presents sample results associated with supplemental investigations (e.g., aqueduct source water sampling) that were concurrently performed in Phase II. Comparisons of data to appropriate risk-based screening levels and regulatory criteria were also presented.

Naples Public Health Evaluation: Naples Italy – Public Health Evaluation Volume II: Phase I & II Screening Risk Evaluation (PIONEER, 2010) – this report presents a screening risk assessment based on the sampling results contained in Volume I and evaluates the potential for impacts to human health from exposure to chemicals in contaminated media (e.g., soil, soil gas, water and ambient air). It also presents the risk drivers associated with residences and study areas under investigation. Uncertainties and limitations involved with this investigation were also presented. In this context, this screening risk assessment is a management decision tool and does not provide absolute statements about health and environmental impacts.

Naples Public Health Evaluation: Naples Public Health Evaluation Public Health Summary: Volume III (Navy and Marine Corps Public Health Center, 2010) – this report integrates the results of Volumes I and II with other information (e.g., Epidemiological Studies) to provide a broader, holistic assessment of the potential public health risks. It also identifies key data gaps and provides recommendations to reduce or eliminate public health risks, where possible.

The PHE was a complex investigation and unique in that the objective was to assess health impacts to USN military and civilian personnel, and their families at an overseas location. This investigation covered a wide geographic area, involved both transient and ill-defined contaminant types and sources, and spanned a period of more than two years. Because of this duration and complexity, different planning documents (e.g., Quality Assurance Project Plans and Work Plans) were prepared and followed during the different phases and aspects of this investigation. These were identified via text and references in the different volumes of this report. Also, because of the duration of the project and in view of the phased approach that was followed, analytical results and the evaluation of these results were provided in different reports and deliverables. The two key deliverables in terms of the results and evaluations of data collected during Phase I of the investigation were: “Final Phase I Environmental Testing Support Assessment Report, Volume I, Naval Support Activity Naples, Italy” and “Naples, Italy–Public Health Evaluation, Volume II: Phase I Screening Risk Evaluation” and the three volumes summarized above.

The approach used in this evaluation was tailored to the unique circumstances found in Naples, Italy and would not necessarily be appropriate for use in other geographic areas.

EXECUTIVE SUMMARY

1.1 Introduction

For decades, the Campania Region of Italy has experienced numerous challenges associated with trash collection, uncontrolled open burning of uncollected trash, and widespread dumping of waste, including chemical and other potentially-hazardous waste. Uncontrolled open burning of uncollected trash is random. In response to health concerns expressed by the United States (U.S.) Navy (USN) and its civilian personnel and families, the Commander Navy Region Europe, Africa, Southwest Asia (CNREURAFSWA) contacted the Navy Bureau of Medicine and Surgery (BUMED) and requested that the Navy and Marine Corps Public Health Center (NMCPHC) conduct a Public Health Evaluation (PHE).

This report documents the findings of the Phase I & II Screening Risk Evaluation (SRE). However, this Executive Summary and the main text of the report focus solely on the results of the Phase II investigation¹. The purpose of the SRE was to determine whether or not there are potential health impacts to USN Personnel (active duty, civil servants, and their family members) residing in the Naples area of Campania that may be associated with exposure to tap water², soil, soil gas (used as an indicator of potential vapor intrusion [VI] to indoor air), and ambient (outdoor) air impacted by improper waste disposal practices. Recognizing that this PHE was a large and unique investigation, the SRE was conducted in accordance with U.S. Environmental Protection Agency (USEPA) Risk Assessment Guidance (USEPA, 1989 - 2009) and USN Risk Assessment Guidance (USN, 2008).

In a typical SRE, a “source” can be identified; however, the Naples PHE was unique in that individual sources could not be identified. The nature of the illicit waste disposal practices that initiated this evaluation presented four confounding issues:

1. Waste disposal locations were often temporary and transitory.
2. In many cases the locations of disposal sites, especially chemical/hazardous waste disposal sites, were not known (Agenzia Regionale per la Protezione Ambientale della Campania [ARPAC], 2009).
3. The contaminant composition was highly variable because the waste was comprised of municipal waste (i.e., trash) and could have potentially also contained chemical waste (see Chapter 12 in the *Report on the Environment in Campania (2009)* [ARPAC, 2009]).
4. The USN could not sample or investigate (e.g., install groundwater monitoring wells, et cetera) potential or suspected areas of contamination resulting from illicit disposal activities as it would, in concert with the appropriate regulatory agencies, in the U.S. Only residences on the Italian economy, where USN Personnel lived (or may live in the future), could be evaluated for risks

¹Appendix F of the report presents the combined results of evaluating the data obtained from all residences sampled on the Italian economy during the PHE.

²At residences sampled during this evaluation, it was apparent that tap water sources included public water, private wells, and blended-water sources. Blended water may have come from non-permitted (illegal) wells that were connected via ancillary piping to the public water-supply system, resulting in a mixture of public water and well water.

(i.e., sampled); therefore, a close correlation between these residences and the potential or suspected areas of contamination could not be derived.

As a result, the approach for this SRE was atypical relative to other environmental investigations performed in the U.S., as these commonly have a known source (e.g., a spill area or industrial emission source), which has a limited and easily defined list of constituents of potential concern (COPCs). This was clearly not the case for this study.

1.2 Investigative History

This PHE focused on the Naples area of Campania where USN Personnel work and live. Since the geographical area being investigated is very large (i.e., approximately 395 square miles), the region was segregated into nine geographical study areas (Figure 2-1). The PHE was completed in two phases. Phase I was conducted between May 2008 and November 2008 and was comprised of two components: 1) a month-long regional ambient air monitoring program at nine air sampling stations, and 2) sampling of tap water (from both private well and municipal water sources), irrigation wells (where available), soil, and passive soil gas from 130 residences (single-family homes and apartments) and 10 U.S. Government-related facilities. Phase II was conducted between November 2008 and October 2009 to improve the spatial/geographic distribution of the sampling locations and to further investigate clusters of residences that exceeded risk criteria during Phase I (Tetra Tech, 2010). Two hundred and nine (209) residences were sampled during Phase II, and the month long ambient air monitoring program from Phase I was continued for one full year. Additional residences were sampled in response to data that were obtained during Phase I and Phase II (e.g., Pre-Lease sampling of 240 residences for tap water, Step-Out sampling of 35 residences proximate to a residence with Unacceptable risk, et cetera). In total, 543 residences were sampled on the Italian economy during the PHE (including both Phase I and Phase II) covering a time period of approximately two and a half years. Tap water, soil, and soil gas samples were collected from residences and analyzed for approximately 241 constituents; tap water samples were also tested for microorganisms (e.g., fecal coliform and total coliforms).

1.3 Conceptual Site Model

A conceptual site model (CSM) provides an understanding of the potential for exposure, under current and future land uses, to constituents within a study area based on the source(s) of contamination, the release mechanism(s), the exposure pathway(s), and the receptor(s). Based on the CSM, the following samples were collected as part of the PHE.

- Tap water samples were collected to assess potential exposures to constituents through drinking, and inhaling vapors while showering, washing dishes, or other household uses of tap water. Constituents can migrate from soil into groundwater wells or other drinking water reservoirs or be introduced via blended water (due to the lack of backflow prevention devices).
- Soil samples were collected to assess potential exposures to constituents through incidental ingestion, inhalation of particulates, and dermal contact with soil. The presence of constituents in soil may be attributable to the deposition of constituents from the open burning of trash or dumping activities, other sources, and/or natural background.

- Soil gas samples were collected to assess whether or not constituents in groundwater and/or soil could potentially volatilize from an undefined subsurface source and migrate through cracks in house foundations and become available for inhalation in indoor air (i.e. a potential VI pathway).
- Ambient air samples were collected to assess potential exposures to constituents related to the inhalation of ambient air.

1.4 Risks Management Categories for Evaluating Incremental Screening Risks

This report characterizes the potential health risks associated with exposure at a residence for 30 years. This is a conservative assumption because tour lengths for USN Personnel stationed overseas typically range from three to six years. However, Department of Defense (DoD) Dependent Schools (DoDDS) personnel can remain at one location for 30 years or longer. Therefore, the USEPA's 30-year standard residential regional screening levels (RSLs) were used in order to ensure that the SRE conservatively assessed potential exposure for all U.S. military or civilian Navy/DoD/DoDDS personnel.

1.4.1 Risk Management Criteria for Evaluating Soil, Soil Gas, and Tap Water

The incremental screening risks associated with exposure to soil, soil gas, and tap water at a residence for 30 years were defined as Acceptable or Unacceptable. The criteria for acceptability are defined in the box below.

Risk-Management Categories for the Public Health Evaluation for Soil, Soil Gas, and Tap Water

Scenario	Criteria for Acceptable Incremental Risks	Criteria for Unacceptable Incremental Risks
Scenario 1 - Tap Water (via Inhalation-Only), Soil, and Soil Gas Exposure	-Total CNCEF less than or equal to 1; and -Total CCEF less than or equal to 10; and -Concentration less than or equal to USMCL (tap water). Applies only to fecal coliform and total coliforms.	-Total CNCEF greater than 1; or -Total CCEF greater than 10; or -Concentration greater than the USMCL (tap water). Applies only to fecal coliform and total coliforms.
Scenario 2 - Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure	-Total CNCEF less than or equal to 1; and -Total CCEF less than or equal to 10; and -Concentration less than or equal to USMCL (tap water). Applies to all COPCs.	-Total CNCEF greater than 1; or -Total CCEF greater than 10; or -Concentration greater than the USMCL (tap water). Applies to all COPCs.
<p>Notes:</p> <p>Noncancer exceedance factors (NCEFs) were calculated by dividing the maximum-detected concentrations by noncancer-based USEPA RSLs. An NCEF of 1 corresponds to a screening Hazard Index (HI) of 1.</p> <p>Cancer exceedance factors (CEFs) were calculated by dividing the maximum-detected concentrations by cancer-based USEPA RSLs.</p> <p>The individual NCEFs and CEFs were summed to provide the cumulative NCEF (CNCEF) and cumulative CEF (CCEF), respectively. A CEF of 1 corresponds to a cancer screening risk of 1E-06 (one in a million). A CEF of 10 corresponds to a cancer screening risk of 1E-05 (one in a 100,000).</p> <p>Total CNCEF is the result of summing the individual NCEFs for all COPCs for all media that were sampled at a residence.</p> <p>Total CCEF is the result of summing the individual CEFs for all COPCs for all media that were sampled at a residence.</p> <p>USMCL: United States Maximum Contaminant Level.</p> <p>Scenario 1 – The tap water RSLs used to evaluate residences that DO NOT use tap water for drinking, cooking, brushing teeth, and making ice were based on inhalation during household uses (e.g., showering) of tap water only. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate.</p> <p>Scenario 2 – The tap water RSLs used to evaluate residences that DO use tap water for drinking, cooking, brushing teeth, and making ice were based on ingestion and inhalation during household uses (e.g., showering, washing clothes) of tap water. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate.</p> <p>The PHE agreed upon approach for this SRE was to evaluate the risks associated with exposure to trihalomethanes (THMs) using the total THM (TTHM) USMCL, rather than individual RSLs. THMs (i.e., bromodichloromethane, chloroform, bromoform, and dichlorobromomethane) are byproducts from disinfecting a water supply, and are typically detected in municipal water supplies. For this evaluation, if the concentration of an individual THM in tap water exceeded the RSL, but was less than the TTHM USMCL, the risk was considered Acceptable.</p>		

1.4.2 Risk Management Criteria for Evaluating Ambient Air

The ambient air samples collected during the PHE reflect general ambient air quality that is impacted by emissions from point (e.g., factory) and non-point (e.g., automobile exhaust) sources (i.e., they were not specific to any industry or source). In the U.S., ambient air quality is regulated via the Clean Air Act (CAA, [U.S. Code, Title 42, Chapter 85]) and this framework was used to evaluate the ambient air results from Naples.

Under the CAA, the USEPA does not use a risk assessment “bright line” (e.g., a cancer risk of 1×10^{-6} to 1×10^{-4} or a hazard quotient greater than 1) to make risk management decisions based on the risks associated with generalized ambient air samples. The USEPA uses a technology-based and performance-based approach to significantly reduce emissions of air toxics from major sources of air pollution, followed by a risk-based approach to address any remaining, or residual risks. These are known as Maximum Achievable Control Technology [MACT] standards. MACT standards:

- consider cost and other non-air-quality factors,
- are based on emissions levels that are already being achieved by the better-controlled and lower-emitting sources in an industry group (i.e., similar industries),
- can be made more stringent by the USEPA when it makes economic, environmental, and public-health sense,
- are based on performance levels (40 CFR Part 63) where industry chooses technology to achieve a performance level that is practicable and cost effective, and
- consider residual risk. Residual risk is evaluated by the USEPA based on residual concentrations of hazardous air pollutants (HAPs) that are emitted to the atmosphere.

The CAA requires a residual risk standard for any source that is emitting a cancer-causing pollutant that poses an added risk of more than 1×10^{-6} to the most exposed receptor, while taking into consideration costs, energy, safety and other relevant factors. HAPs information is used to direct research into new areas where technologies can be developed to improve MACT standards, and consequently reduce risks associated with HAPs.

The cancer and noncancer risks associated with generalized ambient air sampling results are typically used by the USEPA to:

1. identify the chemicals that are responsible for the majority of the risks in ambient air; and
2. identify the major point and non-point sources of those chemicals.

This information is used to help focus research and development so that new pollution control technologies or changes in processes can be used to significantly reduce emissions of these chemicals through the permitting process. In other words, the USEPA recognizes that there will be cancer and noncancer risks associated with emissions from point and non-point sources, but it implements risk management actions at the source (e.g., stack or pipe) rather than at the point of exposure (i.e., the general air we breathe) because it is more feasible/practicable to reduce overall risks at the source or point of release rather than after a chemical has entered the atmosphere.

Italian authorities are responsible for the regulation of Italian air quality standards. The Navy will provide the Italian authorities with the air monitoring results.

1.5 Regional Summary of Incremental Risks for Phase II Residences

Two hundred and nine (209) residences were sampled for tap water, soil, and soil gas during Phase II (although not all media were sampled at every residence). The incremental risks in this SRE were calculated for two different scenarios for all media: (1) assuming tap water exposure via inhalation of vapors only and (2) assuming tap water exposure via ingestion and inhalation. The regional summary of incremental risks by study area for Phase II residences is presented in the box below.

**Number of Residences with Unacceptable Incremental Risks
per Study Area Sampled During Phase II**

Study Area 1	Study Area 2	Study Area 3	Study Area 4	Study Area 5	Study Area 6	Study Area 7	Study Area 8	Study Area 9	All
Scenario 1: Incremental Risks Based on Tap Water (Inhalation-Only), Soil, and Soil Gas									
5 of 30 (17%)	2 of 22 (9%)	0 of 14 (0%)	2 of 14 (14%)	10 of 33 (30%)	5 of 30 (17%)	4 of 24 (17%)	18 of 34 (53%)	0 of 8 (0%)	46 of 209 (22%)
Scenario 2: Incremental Risks Based on Tap Water (Ingestion+Inhalation), Soil, and Soil Gas									
8 of 30 (27%)	13 of 22 (59%)	1 of 14 (7%)	4 of 14 (29%)	15 of 33 (45%)	13 of 30 (43%)	9 of 24 (38%)	24 of 34 (71%)	1 of 8 (13%)	88 of 209 (42%)
Number of Residences Sampled That Obtained Their Water from a Private Well									
0 of 30 (0%)	0 of 22 (0%)	0 of 14 (0%)	0 of 14 (0%)	5 of 33 (15%)	1 of 30 (3%)	0 of 24 (0%)	7 of 34 (21%)	0 of 8 (0%)	13 of 209 (6%)

- Twenty-two percent (46 of 209) of the residences sampled during Phase II had Unacceptable risks based on the Tap Water (Inhalation-Only), Soil, and Soil Gas Scenario.
- Forty-two percent (88 of 209) of the residences sampled during Phase II had Unacceptable risks based on the Tap Water (Ingestion+Inhalation), Soil, and Soil Gas Scenario.

Residences with Acceptable risks and Unacceptable risks were generally randomly distributed within and across the study areas (with some exceptions) and often were located very close to each other (see Figures 4-3 and 4-4).

- The highest number of Unacceptable risks was observed in Study Area 8, where seven of the residences with Unacceptable risks obtained their tap water from a private well.
- Study Areas 3 and 9 had the lowest percentage of Unacceptable risks (for all media) but also had the fewest number of residences sampled; therefore, it is not possible to reach any conclusion regarding the significance of these findings.
- The number and frequency of Unacceptable risks in Study Areas 1 (associated primarily with soil gas) and 2 (associated primarily with tap water) were unexpected because these areas are densely populated and do not have expansive agricultural areas or open space, which could readily be used for illegal waste disposal activities. Volatile COPCs were also frequently detected in municipal tap water from these two study areas. However, historically, periodic and substantial interruptions in trash collection have resulted in the accumulation of large piles of municipal

waste in these densely populated areas which possibly could be associated with the results that were observed (ARPAC, 2009). All of the residences in Study Areas 1 and 2 obtained their tap water from a public source, which is typically less susceptible to contamination associated with localized dumping of waste.

- The majority of the Unacceptable incremental risks identified during Phase II sampling were associated with COPCs detected in tap water from private wells and in soil gas.
 - Summary of Tap Water Risks
 - Scenario 1 – If tap water was not used as a drinking water source (see Figure 4-5):
 - ◆ Twelve (12) of 13 residences (92%) that obtained their tap water from a private well had Unacceptable risks based on inhalation of vapors only.
 - Tetrachloroethene and total coliforms responsible for the majority of the Unacceptable risks in tap water samples obtained from wells.
 - ◆ Seven (7) of 193 residences (4%) sampled for tap water obtained from a public source had Unacceptable risks based on inhalation of vapors only.
 - Total coliforms were responsible for the majority of the Unacceptable risks in tap water samples obtained from a public source.
 - Scenario 2 – If tap water was used as a drinking water source (see Figure 4-6):
 - ◆ Thirteen (13) of 13 residences (100%) that obtained their tap water from a private well had Unacceptable risks based on ingestion and inhalation of vapors.
 - Nitrate, tetrachloroethene, total coliforms, and uranium were responsible for the majority of the Unacceptable risks in tap water samples obtained from wells. However, the concentrations of uranium in tap water did not exceed USMCLs and are most likely associated with natural background concentrations rather than illicit disposal of radioactive waste.
 - ◆ Fifty-one (51) of 193 residences (26%) sampled for tap water obtained from a public source had Unacceptable risks based on ingestion and inhalation of vapors.
 - Lead and total coliforms were responsible for the majority of the Unacceptable risks in tap water samples obtained from a public source.
 - Summary of Soil Gas Risks (see Figure 4-7):
 - ◆ Thirty-two (32) of the 175 residences (18%) that were sampled for soil gas during Phase II had Unacceptable risks based solely on COPCs in soil gas. Clusters of residences with Unacceptable risks associated solely with COPCs detected in soil gas were observed primarily in Study Areas 1, 5, 6, and 8.
 - ◆ Chloroform and tetrachloroethene were responsible for the majority of the Unacceptable risks in soil gas. In addition, the tetrachloroethene results detected in soil gas in Study Area 8 were typically co-located with elevated concentrations of tetrachloroethene in tap water at residences that obtained their tap water from private wells.
 - Summary of Ambient Air Risks
 - ◆ The risks associated with exposure to ambient air in each of the nine study areas were greater than the risks associated with exposure to typical urban air in the U.S. (USEPA, 2007). However, the risks associated with exposure to ambient air in

Naples are not directly comparable to the risks associated with exposure to ambient air in the U.S. because some of the constituents detected in the nine study areas did not have corresponding values in the USEPA's 2007 Air Toxics Database. When those constituents (e.g., 1,2-dibromo-3-chloropropane, which was responsible for, on average, 80% of the cancer risks in each study area) were not included in the calculations of the cumulative EFs, the CCEFs for the nine study areas were less than the typical urban air in the U.S. in all but one study area (i.e., Study Area 8). The CNCEFs did not change appreciably (i.e., the difference was less than one percent) when the cumulative EFs were recalculated using only constituents that had corresponding values in the USEPA's 2007 Air Toxics Database, primarily because acrolein (the constituent that contributed the majority of the CNCEF in the nine study areas) had values in both data sets. Because some constituents (including 1,2-dibromo-3-chloropropane) did not have corresponding values in the USEPA's 2007 Air Toxics Database, it was not possible to determine whether or not the cumulative ambient air risks in the Campania Region exceeded the risks from typical urban air in the U.S.

- ♦ 1,2-Dibromo-3-chloropropane and acrolein were responsible for the majority of the risks in ambient air based on data collected as part of the PHE's year-long ambient air sampling and monitoring program in the Campania Region.

1.6 Summary of the Results from Phase II of the SRE

This section presents general conclusions about the potential health risks associated with living in the Naples area of Campania based solely on the investigative scope, limitations, and results of Phase II of the SRE. These conclusions and any future conclusions, summaries, additional evaluations, and risk management decisions should consider/incorporate the limitations of the PHE risk assessment methodology used, the conservative assumptions incorporated into the SRE (e.g., assumption that a resident lives at a location for 30 years), and the unique conditions/limitations under which the PHE was performed.

This PHE examined the potential health impacts associated with possible exposures to COPCs in tap water (from public sources and private wells), soil, indoor air (via VI from soil gas), and ambient (outdoor air) by USN Personnel residing in the Naples area of Campania. Incremental risks (i.e., risks above background levels) were calculated assuming that a person works and lives in the Naples Areas of Campania for 30 years. This is a conservative assumption because typical USN tour lengths are three to six years; however, some U.S. civilian personnel stay much longer.

In most cases, the risks presented in this SRE were based on a single-sampling event at a specific residence. A single sample only provided a "snapshot" of concentrations that were present in tap water, soil, and soil gas and may or may not be representative of the long-term concentrations at a residence.

In addition, soil gas concentrations were used to predict indoor air concentrations by using a vapor attenuation factor (VAF) to account for the reduction in concentration that occurs when COPC

concentrations in soil gas migrate through cracks and gaps in a residence and the dilution that occurs when the vapors mix with indoor air. Consistent with recommendations from the USEPA, a conservative VAF of 0.1 was used to predict indoor air concentrations from soil gas in the SRE³. This is considered a very conservative assumption because VAFs can range from 0.1 to 0.0001 (or more) depending on groundwater-specific/soil-specific/building-specific characteristics (USEPA, 2008). Therefore, the use of a 0.1 VAF likely overestimated the predicted concentrations in indoor air and the actual risk associated with VI. However, for this SRE it was not appropriate to apply default VAFs that might be less conservative because of the documented variability in VAFs (USEPA, 2008), the lack of groundwater-specific/soil-specific/building-specific characteristics for Naples, and the potential for increased VI migration (i.e. higher VAFs) over the long term as a result of natural (earthquake) or anthropogenic impacts to buildings. There is also potential for decreased VI impacts; though without collecting additional information (tap water, soil gas, and indoor air samples) and knowledge about potential sources, it was necessary to err towards conservatism rather than underestimate the risk.

Two hundred and nine residences (209) were sampled during Phase II of the PHE across nine study areas that were established by the PHE to facilitate the investigation of this large region that encompasses approximately 395 square miles. However, the samples that were collected provide only a single snapshot of the conditions that were present when each residence was sampled. Some of these conditions (e.g., temperature, wind-speed, barometric pressure, et cetera) are transient in nature and can change, sometimes significantly, over time. The temporal variability of conditions and unknowns relating to the: (1) location, number, size (e.g., acres), impacted media (e.g., tap water, soil), and constituents present at chemical/hazardous waste sites in the Campania Region, (2) sources of the tap water supplies, well construction, building parameters, and (3) variability of natural conditions across the Region necessitated that a conservative approach and methodology be adopted for the PHE to ensure that a protective study approach was used for USN Personnel. The potential health risks calculated in the SRE were evaluated using PHE risk management criteria to categorize the exposures at sampled residences as either Acceptable or Unacceptable.

In general, Study Areas 5, 6, and 8 had more Unacceptable risks than other study areas. The number and frequency of Unacceptable risks in Study Areas 1 (associated primarily with soil gas) and 2 (associated primarily with tap water) were unexpected. Study Areas 3 and 9 had the lowest percentage of Unacceptable risks (for all media) but also had the fewest number of residences sampled; therefore, it was not possible to reach any conclusion regarding the significance of these findings.

The key media of concern identified during Phase II of the PHE was soil gas. Thirty-two (32) of the 175 residences (18%) where soil gas samples were collected during Phase II had Unacceptable risks based solely on COPCs in soil gas. Clusters of residences with Unacceptable risks associated solely with COPCs detected in soil gas were observed primarily in Study Areas 5, 6, and 8. Chloroform and tetrachloroethene were responsible for the majority of the Unacceptable risks in soil gas.

³A VAF of 0.1 was applied to all samples to evaluate soil gas, with the exception of multi-story residences that had subsurface ventilated garages or apartment-type dwellings where the resident lived above the ground floor of the structure (i.e., the resident

Tap water from private wells was also of concern. Twelve (12) of 13 residences (92%) that obtained their tap water from a private well had Unacceptable risks based on inhalation of vapors only (assuming that the families are complying with the USN Bottled Water Advisory). These results were primarily observed in Study Areas 5, 6, and 8. If tap water was ingested at these residences that obtained their tap water from a private well, then 13 of 13 residences (100%) had Unacceptable risks.

Tap water from public source(s) was typically Acceptable, whether it was ingested or if it was only used to wash dishes/clothes and bathe/shower. However, low concentrations of COPCs such as lead, tetrachloroethene, total dioxin/furans (2,3,7,8-TCDD toxic equivalents [TEQs]), uranium, and total coliforms were detected at residences that obtained their tap water samples from public sources. Total coliforms are non-volatile and are not of concern to human health via inhalation when present in water. However, these microorganisms were included in the evaluation of risks under the inhalation-only scenario for tap water because they may be accidentally ingested in small quantities during bathing or showering, and even these minimal exposures may result in adverse health effects.

None of the residences (i.e., 0 of 80) where soil samples were collected during Phase II of the PHE had Unacceptable COPC concentrations in soil.

The cancer and noncancer risks associated with ambient air from the Campania Region exceeded the risks calculated from the USEPA's 2007 Air Toxics Database (USEPA, 20007a) for typical U.S. urban air. However, when the risks were calculated using only those constituents that had corresponding values in both data sets, the cancer and noncancer risks were similar. Because some constituents (including 1,2-dibromo-3-chloropropane, which was responsible for, on average, 80% of the cancer risk for ambient air in Naples) did not have corresponding values in the USEPA's 2007 Air Toxics Database, it was not possible to determine whether or not the cumulative ambient air risks in the Campania Region exceeded the risks from typical urban air in the U.S.

lived on the second floor or higher, assuming that the first floor is the ground floor of the building). In these instances a multi-story attenuation factor, assessed and supplied by Tetra Tech NUS, was applied as described in Appendix B.

SECTION 1 – INTRODUCTION

For decades, the Campania Region of Italy has experienced numerous challenges associated with trash collection, uncontrolled open burning of uncollected trash, and widespread dumping of waste, including chemical and other potentially-hazardous waste. Uncontrolled open burning of uncollected trash is random. In response to health concerns expressed by the United States (U.S.) Navy (USN) and its civilian personnel and families, the Commander Navy Region Europe, Africa, Southwest Asia (CNREURAFSWA) contacted the Navy Bureau of Medicine and Surgery (BUMED) and requested that the Navy and Marine Corps Public Health Center (NMCPHC) conduct a Public Health Evaluation (PHE).

This report documents the findings of the Phase I & II PHE Screening Risk Evaluation (SRE)¹. The purpose of the SRE was to determine whether or not there were potential health impacts to USN Personnel (active duty, civil servants, and their family members), residing in the Naples area of Campania that may be associated with exposure to tap water², soil, soil gas (used as an indicator of potential vapor intrusion [VI] to indoor air), and ambient (outdoor) air impacted by improper waste disposal practices. Recognizing that this PHE was a large and unique investigation, the SRE was conducted in accordance with U.S. Environmental Protection Agency (USEPA) Risk Assessment Guidance (USEPA, 1989 - 2009) and USN Risk Assessment Guidance (USN, 2008).

The results of the SRE will be used to determine whether or not risk management actions need to be implemented to protect USN Personnel from potential human health risks, calculated based on USEPA and USN risk assessment guidelines, associated with exposure to tap water, soil, indoor air (via VI from soil gas), and ambient air.

This report utilizes information presented in several documents including:

- *Environmental Testing Support Assessment (ETSA) Work Plan* (Tetra Tech, 2008a),
- *ETSA Field Sampling Plan* (Tetra Tech, 2008b),
- *Phase I ETSA Report: Volume I* (Tetra Tech, 2008c),
- *Naples Italy – Public Health Evaluation Volume II: Phase I Screening Risk Evaluation* (PIONEER Technologies Corporation [PIONEER], 2009),
- *Modeling and Mathematical Analysis of PCE Attenuation between Floors of Multi-Story Dwellings as it Applies to the Public Health Evaluation, Naples, Italy* (Tetra Tech, 2009), and
- *Public Health Evaluation Technical Memorandum: Identification of Chemicals in Soil Gas That May be Associated with Vapor Intrusion* (PIONEER, 2010).
- *Ambient Air Quality and Meteorological Summary Report for the Period July 9, 2008 through July 8, 2009* (Tetra Tech, 2010a),
- *Quality Assurance Project Plan (QAPP)* (Tetra Tech, 2010b),

¹The main text of this report focuses solely on the results of the Phase II evaluation. Appendix F of this report presents an evaluation of the data collected from residences sampled during Phase I and Phase II.

²At residences sampled during this evaluation, it was apparent that tap water sources included public water, private wells, and blended-water sources. Blended water may have come from non-permitted (illegal) wells that were connected via ancillary piping to the public water-supply system, resulting in a mixture of public water and well water.

- *Naples Public Health Evaluation: Phase II Environmental Testing Support Assessment, Public Health Evaluation, Volume I, Naval Support Activity Naples, Italy* (Tetra Tech, 2010c), and
- *Naples Public Health Evaluation: Volume III: Naples Public Health Evaluation Public Health Summary, Naval Support Activity Naples, Italy* (NMCPHC, 2010).

1.1 Investigative History

The PHE was completed in two phases. Phase I was conducted between May 2008 and November 2008 and was comprised of two components: 1) a month-long regional ambient air monitoring evaluation at nine air sampling stations and 2) tap water (from both private well and municipal water sources), irrigation wells (where available), soil, and passive soil gas sampling from 130 residences³ (single-family homes and apartments) and 10 U.S. Government-related facilities. The risk evaluations and results of data collected during Phase I are presented in the *Public Health Evaluation Volume I: Phase I Environmental Testing Support Assessment Report* (Tetra Tech, 2008c) and the *Public Health Evaluation Volume II: Phase I Screening Risk Evaluation* report (PIONEER, 2009). Phase II was conducted between November 2008 and October 2009 to improve the spatial/geographic distribution of the sampling locations and to delineate clusters of residences that exceeded risk criteria during Phase I (Tetra Tech, 2008c). Two hundred and nine (209) residences were sampled during Phase II, and the month-long ambient air monitoring evaluation from Phase I was continued for one full year. For Phase II, active (i.e., SUMMA canisters) sub-slab or near-slab soil gas samples were collected instead of passive (i.e., Gore-Sorber®) samples that were collected during Phase I⁴. Soil sampling was discontinued midway through Phase II because results from Phase I samples indicated that soil contamination did not pose a significant human health risk.

1.2 Site Location and Setting

The Campania Region is located in southwestern Italy and is divided into five provinces: Napoli (Naples), Benevento, Avellino, Caserta, and Salerno (see Figure 1-1 and Figure 1-2). The region has a population of approximately 5.8 million, making it the second most-populated region of Italy. Naples is over 2,800 years old and is the capital city of Campania and the province of Naples. The population of Naples proper is approximately one million.

Campania enjoys a typical Mediterranean climate with mild, wet winters and warm to hot, dry summers. The average low and high temperatures are 52 and 68 degrees Fahrenheit, respectively. The average annual rainfall is 37 inches.

The total area of Campania covers approximately 5,250 square miles. Fifty-one percent of the total area of Campania is hilly, 34% is mountainous and the remaining 15% is made up of plains, which are found to the north in the provinces of Caserta and Benevento. Historically, the Campania Region has had

³The 130 residences included seven pilot study residences.

⁴SUMMA canister soil gas samples provide actual concentration data that are more suitable for evaluation in a risk assessment. In contrast, Gore-Sorber Modules, which are patented, passive-diffusion sorbent-based samplers, measure chemical mass rather than chemical concentration. Consequently, the Gore-Sorber results must be converted to concentrations before they can be used in risk assessments. This conversion results in an estimate of soil gas concentrations which adds to the uncertainty of a risk assessment that is based on these data. Using SUMMA canisters eliminates this conversion and uncertainty and, provides quantitative data for analysis in the risk assessment.

significant volcanic activity. Mount Vesuvius is located on the coast of the Gulf of Naples, approximately six miles east of Naples and the Phlegraean Fields.

Based on topography it can be reasonably inferred that regional groundwater flows towards the west-southwest (Southern Apennine Hydrographic District, 2010). Multiple residential wells have been installed (many suspected to be illegal or installed without a permit) throughout the Region to augment water pressure for households, especially in the summer when the city water pressure is low. This was a significant issue because shallow water supplies are susceptible to chemical and bacteriological contamination.

1.3 Study Areas

This SRE focused on the Naples area of Campania where USN Personnel work and live. Since the area being investigated was very large, the region was divided into nine geographical study areas for the purposes of this evaluation (Figure 1-3). The SRE focused on areas where the density of trash and chemical dump sites were greatest, based on information published by Italian regulators and other host-nation sources^{5,6}. The nine study areas are listed below along with the U.S. Government-related facility that is located within each study area and the approximate size of each study area in square miles. Combined, the study areas comprise approximately 395 square miles:

- Study Area 1 – Joint Forces Command (JFC) North Atlantic Treaty Organization (NATO) Site (approximately 30 square miles)
- Study Area 2 – U.S. Consulate (approximately 15 square miles)
- Study Area 3 – Capodichino (approximately 95 square miles)
- Study Area 4 – Carney Park (approximately 30 square miles) (This facility is located within Study Area 1 but was used to evaluate ambient air for Study Area 4.)
- Study Area 5 – Lago Patria Receiver Site/Parco Artemide (approximately 80 square miles)
- Study Area 6 – Gricignano Support Site (approximately 45 square miles)
- Study Area 7 – Parco Eva (USN-Leased Parco) (approximately 20 square miles)
- Study Area 8 – Villa (home leased by the USN for the PHE) (approximately 30 square miles)
- Study Area 9 – Parco Le Ginestre (USN-Leased Parco) (approximately 50 square miles)

1.4 Overview of the Screening Risk Evaluation Process

Risk assessment is an established scientific approach for evaluating the potential for impacts to human health and the environment associated with exposure to constituents in contaminated media (e.g., water, soil, air). Risk assessments do not provide absolute statements about health and environmental impacts, but rather provide indicators of the likelihood of impacts that may be expected for different types of

⁵This information did not differentiate trash sites from chemical dump sites. Therefore, it was not possible to determine if the residences that were selected for sampling as part of the PHE were near trash sites or chemical dump sites.

⁶Based on Italian maps, six “Sites of National Interest” (similar to the USEPA Superfund Sites on the National Priorities List) were identified in Campania. Of particular concern were the Bagnoli-Coroglio Site of National Interest (for Study Area 2) and the Napoli Orientale Site (for Study Area 3), and the other seven study areas are located within the footprint of the Litorale Domito Flegreo e Agro Aversano Site. These were only the waste sites known by the USN; the majority of the sites were not characterized in terms of extent of contamination, nor remediated (cleaned up). There may be other sites containing urban or hazardous waste that have not yet been documented by Italian agencies.

exposures. Risk assessment is a management decision tool that typically focuses on constituents and exposure pathways directly related to a site. These assessments do not address risks from other sources of exposure (e.g., dietary exposures), or risks from constituents that are not associated with the site under evaluation (e.g., risks from ambient air resulting from automobile exhaust). Risk managers use the results of risk assessments to assist in determining if a site, or a portion thereof, requires further investigation or action (e.g., mitigation, remediation). In an SRE focused on human health impacts, risk-based screening levels for constituents are developed by considering land use, exposed populations, exposure pathways, and toxicity information based on prescribed noncancer and cancer risk goals. SREs are typically comprised of the following three tasks:

1. **Data Analysis.** In this task, constituents are identified from analytical data obtained from the field-sampling program. Constituents detected in at least one sample during the field investigation are identified as constituents of potential concern (COPCs) and are further evaluated in the SRE.
2. **Conceptual Site Model and Identification of Risk-Based Screening Levels.** In this task, screening levels (i.e., constituent concentrations that are protective of human health) are identified based on the exposure pathways and routes of exposure associated with the site being evaluated. Noncarcinogenic (noncancer) constituent screening levels are established at concentrations that are presumed not to cause illness in humans. Carcinogenic (cancer) constituent screening levels are established at concentrations that do not cause exceedances of the allowable level of excess cancer risk (following USEPA and USN Risk Assessment Guidance) in humans (USEPA, 1989; USN, 2008).
3. **Risk Evaluation: Comparison of Site Media Concentrations to Risk-Based Screening Levels.** In this task, site media concentrations identified and summarized in Task 1 are compared with the risk-based screening levels identified in Task 2. Consistent with USEPA risk assessment guidance, the results of an SRE may be expressed as exceedances of the risk-based screening levels.

In a typical SRE, a “source” can be identified; however, the Naples PHE was unique in that individual sources could not be identified. The nature of the illicit waste disposal practices that initiated this evaluation presented four confounding issues:

1. Waste disposal locations were often temporary and transitory.
2. In many cases the location(s) of disposal sites, especially chemical/hazardous waste disposal sites, was not known (Agenzia Regionale per la Protezione Ambientale della Campania [ARPAC], 2009).
3. The contaminant composition was highly variable because the waste was comprised of municipal waste (i.e., trash) and could have potentially contained chemical waste (see Chapter 12 in the *Report on the Environment in Campania (2009)* [ARPAC, 2009]).
4. The USN could not sample or investigate (e.g., install groundwater monitoring wells, et cetera) potential or suspected areas of contamination resulting from illicit disposal activities as it would, in concert with the appropriate regulatory agencies, in the U.S. Only residences on the Italian economy where USN Personnel lived (or may live in the future) could be evaluated for risks (i.e.,

sampled); therefore, a close correlation between these residences and the potential or suspected areas of contamination could not be derived.

As a result, the approach for this SRE was atypical relative to other environmental investigations performed in the U.S., as these commonly have a known source (e.g., a spill area or industrial emission) which typically have a limited and easily defined list of COPCs. This was clearly not the case for this SRE.

1.5 Report Organization

This report is organized as follows:

- Section 2.0 – Data Analysis
- Section 3.0 – Conceptual Site Model and Identification of Risk-Based Screening Levels
- Section 4.0 – Risk Evaluation: Comparison of COPC Concentrations to Risk-Based Screening Levels
- Section 5.0 – Uncertainty Analysis

Tables and figures are presented in separate sections following the text and prior to the appendices. The sections in this report are supplemented by appendices that provide supporting documentation of items discussed in the text.

SECTION 2 – DATA ANALYSIS

This section identifies sources of data and the constituents detected in tap water, soil, soil gas, and ambient air samples that were collected from the nine study areas, which were further evaluated in the SRE.

2.1 Sources of Data

The objective of the environmental sampling performed during Phases I and II of the SRE was to determine whether or not risk management actions need to be implemented to protect USN Personnel from potential human health risks, calculated based on USEPA and USN risk assessment guidelines, associated with exposure to tap water, soil, indoor air (via VI from soil gas), and ambient air (USEPA, 1989; USN, 2008). A comprehensive, multi-media sampling program began in May 2008 to identify contamination in tap water, soil, soil gas, and ambient air in the nine study areas identified within the Campania Region.

2.1.1 Sampling Events

There were five major sampling events conducted as part of the Naples PHE:

1. **Phase I Sampling** – One-hundred and thirty (130) residences and 10 U.S. Government-related facilities were sampled from May 2008 through November 2008 during Phase I for tap water, soil, and soil gas (see Figure 2-1) (Tetra Tech, 2008a and PIONEER, 2009). A Pilot Study was conducted at seven of the 130 residences to evaluate sampling procedures and logistical details to improve the efficiency of the Phase I *ETSA Field Sampling Plan* (Tetra Tech, 2008b). For the Pilot Study, tap water, soil, passive soil gas and ambient air samples were collected. The results for these seven Pilot residences were subsequently incorporated into the Phase I evaluation.

A biased sampling design was implemented for Phase I in order to sample areas within the Naples area of Campania, where USN Personnel work and live, that available information suggested had the highest potential of being impacted by the effects of hazardous waste that had been disposed of improperly. Italian maps showing the locations of documented trash and chemical dump sites⁷ were reviewed (see Figure 2-1) to identify candidate residences for sampling from these presumed "worst-case" areas that were occupied by USN Personnel.

2. **Pre-Lease Sampling** – Two-hundred and forty (240) residences were sampled from September 2008 through January 2009 during Pre-Lease Sampling (see Figure 2-1). The Phase I SRE (PIONEER, 2009) indicated that volatile organic compounds (VOCs) and bacteria in tap water (primarily from private wells) were of concern to human health. Based on the results of the Phase I SRE, the USN instituted a policy that required the sampling of tap water at residences located on the Italian economy prior to occupancy by USN Personnel. If the health risks associated with

⁷These maps did not differentiate trash sites from chemical dump sites. Therefore, it was not possible to determine if the residences that were selected for sampling as part of the PHE were near trash sites or chemical dump sites.

tap water were found to be Acceptable according to the PHE risk management criteria⁸, then USN Personnel were allowed to sign the lease and move into the residence. If the health risks associated with tap water were considered to be Unacceptable according to the PHE risk management criteria, then USN Personnel were not allowed to move into the residence and the residence was removed from the USN Naples Housing List.

3. **Year-Long Ambient Air Sampling (Phase I and Phase II)** – A year-long ambient air sampling and monitoring program was performed that spanned both Phase I and Phase II of the PHE. The objective of the ambient air sampling event was to characterize air quality for the nine study areas, which involved the construction and operation of nine air sampling stations, a continuous air monitoring station, and a meteorological monitoring tower. Over 92,000 individual analyses for 211 constituents were performed during this one-year period. Tens of thousands of continuous monitoring measurements for criteria pollutants and meteorological parameters were also obtained and evaluated (Tetra Tech 2010a).
4. **Step-Out Sampling** – Thirty-six (36) residences were sampled from September 2008 through August 2009 during the Step-Out Sampling Event (see Figure 2-1). Step-Out sampling was performed as part of the PHE to determine whether or not residences located proximate to a residence with Unacceptable risks, based on the PHE risk management criteria, had Acceptable or Unacceptable risks. Residences located within 500 feet of the initial residence that had an Unacceptable risk were sampled to determine whether or not additional actions were necessary at these residences⁹. If the risks at residences sampled during the first Step-Out sampling were Unacceptable, then additional Step-Out sampling was performed (typically in 500-foot increments¹⁰) in the direction where the new Unacceptable risks were identified. If the risks at residences sampled during the initial round of Step-Out sampling were Acceptable, then no additional Step-Out sampling was necessary.

Phase II sampling locations were selected to obtain broad geographical coverage and to analyze for a broad range of constituents across the sampled media (tap water, soil, soil gas, and ambient air). If sampling results identified an Unacceptable risk, it would not, in general, be possible to ascertain the proximity of that residence to a known “source.” Stepping out in the direction of all compass points provided a better approach for evaluating the extent of concern at that residence¹¹.

⁸The PHE risk management criteria used to determine Unacceptable risks are presented in Section 4.3 of this report.

⁹The 500-foot Step-Out distance was based on VI and other guidance documents that recommend additional investigation for areas within 100 feet of the edge of a known and documented subsurface contamination source. Due to a lack of information regarding the size or characteristics of the vapor or presumed-to-be impacted groundwater in the study areas, and the relative location of the residence with Unacceptable risk within the study areas, a Step Out distance of 500 feet was used to err on the side of being protective and to demonstrate that residences within this distance had an Acceptable risk.

¹⁰However, during the second Step-Out Sampling Event that was performed in Study Area 8, the USN PHE Team decided to increase the Step-Out distance to 1,500 feet because the sampling results from all of the residences included in the initial 500-foot Step-Out Sampling Event were Unacceptable.

¹¹In the U.S., it is common practice to utilize Step-Out sampling in environmental investigations to determine the extent of contamination in a geographic area where a contaminant source is documented and under investigation. This method selects sampling locations a specific distance (potentially in all directions) from the initial location where there is identified contamination, with the goal of determining the extent of contamination. For the PHE, if there was contamination in the Step-Out samples attributable to the same constituent that was responsible for “triggering” the Step-Out Sampling Event, field personnel collected subsequent rounds of Step-Out samples further from the residence that triggered the Step Out until sample results were Acceptable.

5. **Phase II Sampling** – Two-hundred and nine (209) residences and 10 U.S. Government-related facilities were sampled from November 2008 through October 2009 during Phase II (see Figure 2-1). Of the 209 residences, 139 were new residences that had not been sampled during previous events, 70 were previously sampled during Phase I, Pre-Lease, or Step-Out Sampling Events and were re-sampled again during Phase II – typically only for media that were not sampled during previous events. Phase II sampling was designed based on the results of Phase I to improve the spatial/geographic distribution of sampling locations and to potentially delineate clusters of residences that exceeded risk criteria.

In addition, active soil gas, ambient air, and indoor air samples were collected at Capodichino and the Gricignano Support Site as part of a VI investigation (Tetra Tech, 2009). Active soil gas samples were also collected at Parco Eva and Parco Le Ginestre to investigate the potential for VI from soil gas to impact indoor air. Indoor air samples were collected from the Villa in Study Area 8 that was leased in support of the PHE.

2.1.2 Media Sampled

Sampling objectives, sampling methodologies, analytical methods, and quality assurance/quality control procedures, are documented in the

- *ETSA Work Plan* (Tetra Tech, 2008a),
- *ETSA Field Sampling Plan* (Tetra Tech, 2008b),
- *Phase I ETSA Report: Volume I* (Tetra Tech, 2008c),
- *Ambient Air Quality and Meteorological Summary Report for the Period July 9, 2008 through July 8, 2009* (Tetra Tech, 2010a),
- *QAPP* (Tetra Tech, 2010b), and
- *Naples Public Health Evaluation: Phase II Environmental Testing Support Assessment, Public Health Evaluation, Volume I* (Tetra Tech, 2010c).

The following media were sampled as part of the PHE:

Media	Phase I	Pre-Lease	Step-Out	Phase II
Tap Water¹	Yes	Yes	Yes	Yes
Surface Soil Composite surface soil (zero to six inches below ground surface [bgs]) (for all analyses except VOCs); Discrete surface soil samples (for VOCs only).	Yes	No	No	No (a few Phase II residences had soil samples collected before the soil sampling was discontinued)
Passive Soil Gas (Gore-Sorber) Collected near-slab from less than five feet bgs.	Yes	No	No	No
Active Soil Gas (SUMMA canister) Collected near-slab or sub-slab from less than five feet bgs.	No	No	Yes	Yes
Ambient Air (from residences)	Yes (selected residences)	No	Yes (selected residences)	Yes (selected residences)
Ambient Air Collected at U.S. Government-related facilities as part of the one-year ambient air monitoring evaluation.	Yes	Yes	Yes	Yes

Notes:

¹Samples were also collected from irrigation wells.

Indoor air samples were also collected at Capodichino and the Gricignano Support Site as part of a VI investigation (Tetra Tech, 2009)

In general, samples were analyzed for approximately 241 constituents¹² (i.e., chemicals, microorganisms, and radionuclides) from the following analytical classes:

Analysis	Phase I	Pre-Lease	Step-Out	Phase II
Aldehydes and Ketones (residential and regional ambient air samples only)	Yes	No	Yes (active soil gas)	Yes
Alkane Hydrocarbons (Phase I passive soil gas samples and regional ambient air samples only)	Yes	No	No	No
Anions (tap water samples only)	Yes	Yes (most residences)	Yes	Yes
Conventional Parameters (tap water samples only)	Yes	Yes	Yes	Yes
Dioxins/Furans (2,3,7,8-Tetrachlorodibenzo-p-dioxin [2,3,7,8-TCDD])	Yes	Yes (most residences)	Yes	Yes
Disinfectants and Disinfectant Byproducts (tap water samples only)	Yes	Yes	Yes	Yes
Field Parameters (tap water samples only)	Yes	Yes	Yes	Yes
Inorganics	Yes	Yes (most residences)	Yes	Yes
Microorganisms (tap water samples only)	Yes	Yes	Yes	Yes
Particulate Matter less than 10 microns in diameter (PM ₁₀) (regional ambient air samples only)	Yes	No	No	Yes
Pesticides	Yes	Yes (most residences)	Yes (until discontinued)	Yes (until discontinued)
Polychlorinated Biphenyls (PCBs)	Yes	Yes (most residences)	Yes (until discontinued)	Yes (until discontinued)
Radionuclides (tap water samples only)	Yes	Yes (most residences)	Yes	Yes
Semi-Volatile Organic Compounds (SVOCs)	Yes	Yes (most residences)	Yes (until discontinued)	Yes (until discontinued)
VOCs	Yes	Yes	Yes	Yes

Tap water, soil, and soil gas samples were collected from multiple residences located throughout the nine study areas (see Table 2-1 and Figure 2-1) (Tetra Tech, 2008a and 2008c). In most cases, the risks presented in this SRE were based on a single-sampling event at a residence. Sampling was almost always limited to one sample per medium and it was rarely an option to return and collect additional samples. As discussed in Section 5.2.2, a single sample only provides a "snapshot" of concentrations that are present in tap water, soil, and soil gas and may not be representative of the long-term concentrations at a residence. Not all media could be sampled at every residence (e.g., if the residence did not have a yard or the yard was inaccessible, then soil samples could not be collected). It should be noted that as the distance from sampled residences increases, the representativeness of these sampling results to other residences decreases.

¹²The number of constituents may vary depending on the medium being analyzed.

2.1.2.1 Tap Water

Tap water samples were evaluated to determine whether or not potential exposures existed via ingestion and inhalation (i.e., breathing vapors released during tap water use [e.g., showering/bathing]). It was hypothesized that due to a lack of backflow prevention mechanisms, tap water could potentially be contaminated by constituent infiltration into the distribution lines, or through direct contact with a contaminant source.

Tap water samples were collected from the faucet normally used for household purposes (e.g., a kitchen or bathroom faucet). The tap water that was sampled originated from either the municipal water supply (public water) or private drinking or irrigation wells (private wells). The results from irrigation wells were not used to calculate risks at residences sampled on the Italian economy.

2.1.2.2 Soil

Soil samples were evaluated to identify potential constituent concentrations in soil resulting from the deposition of contaminants that may be related to the open burning of trash or illegal dumping activities. Soil was evaluated to assess potential exposures to USN Personnel through incidental ingestion, inhalation of particulates, and dermal contact.

Soil samples were collected at all residences with an accessible yard during Phase I and at some residences during Phase II. Soil sampling was discontinued during Phase II because the Phase I results overwhelmingly indicated that soil contamination did not pose a significant health risk. Composite samples (to depths not exceeding six inches bgs) were collected and analyzed for all constituents except for VOCs (Tetra Tech, 2008c). Discrete soil samples were collected and analyzed for VOCs.

2.1.2.3 Soil Gas

Soil gas samples were evaluated to assess potential impacts to human health via the inhalation pathway resulting from COPCs in groundwater or soil volatilizing, and then entering a home through cracks in the home's foundation, potentially adversely-impacting indoor air. For Phase I of the SRE, soil gas samples were collected using Gore-Sorber Modules, which are patented, passive-diffusion sorbent-based samplers that collect VOC, SVOC, and pesticide samples. The Gore-Sorber Modules were placed under the ground surface adjacent to the residence being sampled, at an approximate depth of 18 inches, and remained in place for a minimum of 24 hours. The passive soil gas collection process measures the constituent mass rather than the concentration. Hence, soil gas concentrations were estimated by Gore using the mass of constituents detected, in combination with general information obtained from scientific literature regarding the soil type (e.g., volcanic soil) in the Campania Region. During all subsequent soil gas sampling events (Step-Out and Phase II), active soil gas samples were collected from residences using 6-liter SUMMA canisters over a time period of 30 to 60 minutes. Sub-slab soil gas samples were collected from two to four inches beneath the floor slab of a garage or basement unless conditions prohibited access. Otherwise, near-slab soil gas samples were collected within 10 feet of the residence, at

approximately five feet bgs. Active soil gas samples were analyzed for VOCs and select SVOCs using USEPA Method TO-15⁽¹³⁾.

The intent during Phase II was to collect sub-slab soil gas samples at all candidate residences; however, it was not possible to collect sub-slab soil gas samples at all residences (e.g., tenants lived in upper floors with no access to ground floor areas, or in some cases landlords refused to permit sub-slab soil gas sampling). In these instances, near-slab soil gas samples were collected. Approximately 51% of the active soil gas samples that were collected were sub-slab samples.

COPCs potentially associated with VI (i.e., VI COPCs) were classified as either Global or Localized VI COPCs in the soil gas evaluation performed in 2009. The approach used to delineate potential VI COPCs was documented in the *Technical Memorandum: Identification of Chemicals in Soil Gas That May be Associated with Vapor Intrusion*, which is Appendix D of this volume (and appendix C.2 of the May 2010 QAPP). Global VI COPCs¹⁴ were evaluated for the VI pathway at all residences. Localized VI COPCs were evaluated for the VI pathway at residences where the soil gas concentration exceeded the 95th percentile site-wide ambient air concentration for that COPC. If the soil gas concentration was less than or equal to the 95th percentile site-wide ambient air concentration, then the COPC was not evaluated for soil gas risks using soil gas data but was evaluated for ambient air risks using ambient air data. If the COPC was detected in soil gas at a concentration greater than the 95th percentile of the site-wide ambient air concentration, then the COPC was evaluated for soil gas risks using soil gas data and also for ambient air risks using ambient air data (PIONEER, 2009).

2.1.2.4 Ambient Air

Ambient air samples were evaluated to assess potential exposures via the inhalation of ambient (i.e., outdoor) air impacted by typical urban point sources, non-point sources, and random burning of trash in areas of the Campania Region. Under typical conditions, there is significant movement and mixing of ambient air over large areas. Consequently, concentrations of constituents in ambient air are more regional in nature than concentrations of constituents in tap water, soil, and soil gas. Therefore, the ambient air results from one sampling station can reasonably be assumed to apply to multiple residences in the vicinity of the air sampling station.

During Phase I of the SRE, five ambient air samples were collected over a 30-day period from each of the nine study areas and a private residence. During Phase II, ambient air samples were collected from the nine study areas as part of the year-long ambient air sampling and monitoring program. Air samples were collected at the nine air sampling stations every nine days for approximately the first seven months, and then every six days for the remainder of the evaluation. Because the burning of trash is random, a nine-day sampling period between sample collections at each station was employed to ensure that the sampling was not biased toward any specific day of the week. In other words, the goal of the air sampling program

¹³During Phase II, naphthalene and acetaldehyde were among the constituents tested for in active soil gas and ambient air via USEPA Methods TO-13A and TO-15 for naphthalene and TO-11 and TO-15 for acetaldehyde. Inconsistencies in the results between the two methods (TO-13A and TO-15 for naphthalene and TO-11 and TO-15 for acetaldehyde) led to further research and Tetra Tech determined that the active soil gas (and select ambient air) data for naphthalene and acetaldehyde analyzed by the USEPA Method TO-15 were not suitable for inclusion in the SRE. See Section 5.2.7 for a detailed discussion of naphthalene/acetaldehyde data.

¹⁴Global VI COPCs and Localized VI COPCs are listed in Section 4.2 and are presented in Appendix D of this report.

was to collect air samples on different days of the week so that representative annual air concentrations could be calculated for evaluation in the SRE (Tetra Tech, 2008a; Tetra Tech, 2008c; and Tetra Tech, 2010b). The nine U.S. Government-related facilities where ambient air samples were collected are located in the following study areas.

- Study Area 1 – JFC NATO Site
- Study Area 2 – U.S. Consulate
- Study Area 3 – Capodichino
- Study Area 4 – Carney Park (This facility is located within Study Area 1 but was used to evaluate air for Study Area 4)
- Study Area 5 – Lago Patria Receiver Site
- Study Area 6 – Gricignano Support Site
- Study Area 7 – Parco Eva (USN-Leased Parco)
- Study Area 8 – Villa (Home leased by the USN for the PHE)
- Study Area 9 – Parco Le Ginestre (USN-Leased Parco)

The SRE includes the results presented in the *Ambient Air Quality and Meteorological Summary Report for the Period July 9, 2008 through July 8, 2009* (Tetra Tech, 2010a) in addition to the results from all ambient air samples that were collected from individual residences or at U.S. Government-related facilities.

2.1.2.5 Differences Between Phase I and Phase II

Phase II sampling was influenced by information obtained during the Phase I investigation. Important changes/modifications that were implemented between the Phase I and Phase II Sampling Events are summarized below:

- Soil sampling was discontinued because Phase I and preliminary Phase II soil sampling results indicated that concentrations were not of concern to human health.
- Phase I tap water results (from public water and private wells) revealed that SVOC and pesticide concentrations did not exceed screening levels; hence, these chemicals were not evaluated during Phase II. Phase I tap water results indicated that gross-beta concentrations exceeded screening levels. Therefore, radionuclide speciation of Phase II tap water samples was conducted if the established gross-alpha or gross-beta analytical trigger levels were exceeded.
- During Phase I, passive soil gas results revealed concentrations of VOCs that exceeded screening levels, with the potential for VI from soil gas to indoor air. Passive soil gas results can be semi-quantitative, but are typically more qualitative in nature. To achieve more quantitative soil gas data, some residences that had Unacceptable results during Phase I (with the exception of residences considered Unacceptable based on coliforms or soil results only) were re-sampled during Phase II by collecting active soil gas samples. In addition, only active soil gas samples were collected from residences during Phase II.
- Co-located active soil gas samples and residential ambient air samples were collected at some residences to provide perspective, and to provide an additional line of evidence for evaluating active soil gas results.

Figure 2-1 presents the U.S. Government-related facilities and Table 2-2 presents the number of samples collected by medium at the U.S. Government-related facilities which were evaluated in the Phase I SRE (PIONEER, 2009).

2.2 Data Processing Prior to Analysis

The analytical data for tap water, soil, soil gas, and ambient air were analyzed and a preliminary list of COPCs was identified for each medium based on whether or not the constituent was detected in at least one sample at one location.

Analytical data were converted to useable formats for the SRE as follows:

- Data were only evaluated for constituents that were detected in at least one sample at a specific location. Analytical results that were qualified “R” (i.e., rejected) were eliminated from the data set because the data did not meet quality-control criteria.
- The total dioxins/furans (2,3,7,8-tetrachlorodibenzo-p-dioxin [2,3,7,8-TCDD]) toxic equivalent (TEQ¹⁵) concentration was calculated for each sample based on the analytical results of the isomers and congeners of dioxins and furans. This calculation was performed by multiplying the concentration of the isomers/congeners by their corresponding 2005 World Health Organization (WHO) 2,3,7,8-TCDD toxicity equivalency factors (TEFs) and then summing the results (Van den Berg, 2006). Nondetected results for individual congeners were not included in the 2,3,7,8-TCDD TEQ calculations. The 2,3,7,8-TCDD TEFs are presented in Table 2-3.
- The total benzo(a)pyrene (BaP) toxic equivalent concentration (BaP TEQ) total carcinogenic polycyclic aromatic hydrocarbons (cPAHs) was calculated for each sample based on the analytical results of all cPAHs. This calculation was performed by multiplying the concentration of the cPAH by its corresponding BaP TEF and then summing the results (USEPA, 1989). Nondetected results for individual cPAHs were not included in the BaP TEQ calculations. The BaP TEFs are presented in Table 2-4.
- The total trihalomethane (TTHM) concentration was calculated for tap water samples only by summing the detected results for bromodichloromethane, chloroform, bromoform, and dichlorobromomethane.
- The total xylenes concentration was calculated for all samples by summing the detected results for all xylene isomers (i.e., ortho, meta, and para).

Table 2-5 identifies constituents that were detected in at least one sample in each medium (i.e., tap water [from irrigation, private well, and/or municipal tap water], soil, soil gas, and ambient air). These COPCs were further evaluated in this SRE.

¹⁵TEQ concentrations are inherently more uncertain than the actual concentrations reported by the laboratory.

SECTION 3 – CONCEPTUAL SITE MODEL AND IDENTIFICATION OF RISK-BASED SCREENING LEVELS

This section presents the conceptual site model (CSM) for the nine study areas and identifies risk-based screening levels that were used to calculate risks for receptors (e.g., workers and residents) identified in the CSM.

3.1 Conceptual Site Model

A CSM provides an understanding of the potential for exposure, under current and future land uses, to constituents within a study area based on the source(s) of contamination, the release mechanism(s), the exposure pathway(s), and the receptor(s). The CSM for the nine study areas is presented on Figure 3-1 and discussed below.

The sources and release/transport mechanisms of contamination to be evaluated in the SRE are as follows:

- Source of Contamination – Dumped and Burned Trash Throughout the Campania Region
 - Release/transport mechanisms:
 - Vapors and particulates released to the air via burning trash are then transported via wind
 - Particulates in the air are deposited onto soil and surface water
 - Constituents deposited on soil may leach from soil into underlying groundwater
- Source of Contamination – Point (e.g., exhaust from power plants and factories) and Non-Point (e.g., automobile exhaust) Combustion Sources in the Campania Region
 - Release/transport mechanisms:
 - Vapors and particulates released into the air are then transported via wind
 - Particulates in the air are deposited onto soil and surface water
 - Constituents deposited on soil may leach from soil into underlying groundwater
- Source of Contamination – Legal and Illegal Dumping of Waste (Including Chemical Waste)
 - Release/transport mechanisms:
 - Constituents deposited on soil may leach from soil into underlying groundwater
 - Volatile constituents may volatilize from soil and/or groundwater into ambient air or the indoor air of buildings
 - Particle-bound constituents in soil may be transported into the air via entrainment subsequent to erosion due to wind

The complete exposure pathways evaluated in the SRE included the following:

- Inhalation of vapors and particulates in ambient air emitted from combustion sources (e.g., burning of trash, exhaust from power plants and factories, and automobile exhaust)
- Incidental soil ingestion
- Dermal contact with soil
- Inhalation of vapors and particulates in air emitted or dislodged from soil

- Inhalation of vapors in indoor air associated with VI from undefined groundwater and/or soil contaminant sources
- Ingestion of tap water, which may be provided by the city and/or by a well on the property
- Inhalation of vapors in indoor air associated with household uses of tap water (e.g., showering & washing dishes)

The following potentially-complete exposure pathways were not included in the SRE:

- Dermal contact with tap water (which may be provided by the city and/or by a well on the property). The PHE Project Team decided during the QAPP process to use USEPA tap water RSLs to evaluate risk in this SRE (Tetra Tech, 2010). Because the USEPA tap water RSLs do not incorporate dermal contact with tap water, this pathway was not evaluated in the PHE.
- Ingestion of fruits, vegetables, meat and dairy products associated with potentially-impacted soil. These exposure pathways were not quantitatively evaluated in the SRE but were assessed in the *Naples Public Health Evaluation: Naples Public Health Evaluation Public Health Summary: Volume III* (NMCPHC, 2010).
- Ingestion of surface water, dermal contact with surface water, and ingestion of biota impacted by bio-uptake of contaminants associated with potentially-impacted soil. The PHE Project Team was only able collect samples from residences on the economy where USN Personnel live. For this reason, this pathway was not evaluated in the SRE and is considered a data gap.

The following potentially-exposed populations living and/or working in the study areas were evaluated for this report:

- USN Personnel (military and civilian) and their families
- Department of Defense (DoD) and DoD Dependent Schools (DoDDS) personnel and their families
- U.S. State Department personnel and their families

The following potentially-exposed populations living and/or working in the study areas were not evaluated for this report:

- Other private U.S. citizens and their families
- Italian citizens
- Other, non-Italian, foreign nationals

Based on the CSM the following samples were collected as part of the PHE.

- Tap water samples were collected to assess potential exposures to constituents through ingestion and inhalation of vapors that volatilize from tap while showering and through other household uses (e.g., washing clothes, dishes, et cetera). Constituents can migrate from soil into groundwater wells, other drinking water reservoirs, or via blended water (due to the lack of backflow prevention devices).
- Soil samples were collected to assess potential exposures to constituents through incidental ingestion, inhalation of particulates, and dermal contact with soil. The presence of constituents in soil may be attributable to the deposition of constituents from the open burning of trash or dumping activities, other sources, and/or natural background.

- Soil gas samples were evaluated to assess potential impacts to human health via the inhalation pathway resulting from constituents in groundwater or soil volatilizing, and then entering a home through cracks in the home's foundation, potentially adversely impacting indoor air.
- Ambient air samples were collected to assess potential exposures to constituents related to the inhalation of ambient air.

3.2 Identification of Risk-Based Regional Screening Levels

Risks were calculated for this SRE by comparing exposure point concentrations (EPCs)¹⁶ for tap water, soil, soil gas, or ambient air with December 2009 USEPA 30-Year Residential Regional Screening Levels (RSLs) (USEPA, 2009) (see Tables 3-1 [tap water], 3-2 [soil], and 3-3 [ambient air]). The use of 30-Year Residential RSLs in the SRE is conservative because USN tour lengths are typically three to six years; however, DoDDS personnel can remain at one location for 30 years or longer. Therefore, the USEPA's 30-year standard residential RSLs were used in order to ensure that the SRE was protective of the reasonable maximum exposure (RME) individuals (i.e., DoDDS personnel).

RSLs are constituent concentrations derived from equations that combine exposure assumptions with constituent-specific toxicity values and are based on carcinogenic or systemic toxicity values under specific exposure conditions. The USEPA 30-Year Residential RSLs were calculated using default exposure parameters and factors that represent RME conditions for long-term/chronic exposures and are based on the methods outlined in the USEPA's Risk Assessment Guidance for Superfund, Part B Manual (USEPA, 1991) and Soil Screening Guidance documents (USEPA, 1996 and USEPA, 2002b). Even though RSLs are published for soil and air for industrial workers, only the 30-year Residential RSLs for tap water, soil and ambient air were used in this SRE because they are protective of these other exposure scenarios. The equations and input parameters used to develop these USEPA RSLs are documented in Appendix A. Soil gas RSLs were derived from the USEPA's standard 30-Year Residential RSLs by dividing the residential ambient air RSLs by the USEPA's default vapor attenuation factor (VAF) of 0.1 (USEPA, 2002a).

Inhalation risks potentially associated with VI of constituents in soil gas to indoor air can vary by orders of magnitude depending on the degree of the attenuation that occurs between soil gas and indoor air (Tetra Tech, 2009). Subsurface conditions and building characteristics vary across the nine study areas, and because access to residences was not always possible, some soil gas samples were collected sub-slab and some were collected outside of the building (near-slab). However, all soil gas sample concentrations, regardless of how they were collected, were compared to RSLs that were calculated using the USEPA's default VAF (α) of 0.1¹⁷ (normally used for sub-slab soil gas), which was also the VAF specified in the QAPP (Tetra Tech, 2010). VI studies and empirical data have shown that applying a VAF of 0.1 was a very conservative assumption (see Section 5.4). However, because groundwater-specific/soil-specific/building-specific characteristics were not available (or were not collected at the time of sampling)

¹⁶An EPC is the concentration of a constituent in tap water, soil, indoor air (via VI from soil gas), or ambient air at the location of potential contact with the receptor (i.e., individual). EPCs are explained in Section 4.1.

¹⁷A VAF of 0.1 was applied to all samples to evaluate soil gas, with the exception of multi-story residences that had subsurface ventilated garages or apartment-type dwellings where the resident lived above the ground floor of the structure (i.e., the resident

in the Campania Region, it was not appropriate to develop site-specific VAFs that might be less conservative.

For lead, RSLs for tap water, soil, and ambient air were developed using the USEPA's Integrated Exposure Uptake Biokinetic (IEUBK) Model (USEPA, 2007).

The following additional screening levels were also included in this evaluation:

- For tap water, the U.S. Maximum Contaminant Levels (USMCLs) (see Table 3-1) (40 Code of Federal Regulation [CFR] Part 141) (<http://www.epa.gov/safewater/contaminants/index.html>)
- For air, the U.S. National Ambient Air Quality Standards (NAAQS) (see Table 3-3) (40 CFR Part 50) (<http://www.epa.gov/air/criteria.html>).

lived on the second floor or higher, assuming that the first floor is the ground floor of the building). In these instances a multi-story attenuation factor, assessed and supplied by Tetra Tech NUS, was applied as described in Appendix B.

SECTION 4 – RISK EVALUATION: COMPARISON OF COPC CONCENTRATIONS TO RISK-BASED SCREENING LEVELS

This section presents the results of the risk calculations performed for the SRE. In most Superfund risk assessments, risks are calculated by integrating the results of the exposure assessment and toxicity assessment into a quantitative estimate of noncarcinogenic hazard indices and carcinogenic risks. In this SRE, risks were determined by comparing COPC concentrations to RSLs, and calculating exceedance factors (EFs), which are the ratio of a COPC's EPC to its RSL. Concentrations of COPCs in tap water, soil, soil gas, and ambient air that exceeded RSLs (i.e., COPCs with EFs greater than one) may be of concern to human health. Cancer EFs (CEFs) and noncancer EFs (NCEFs) were calculated separately and were summed by each medium to determine cumulative CEFs (CCEFs) and cumulative NCEFs (CNCEFs). CCEFs and CNCEFs were summed to determine the Total CCEF or Total CNCEF for a receptor at a sample location (i.e., residence). The methodology for calculating EFs is described in detail in Section 4.2.

As described in Section 3, risks were calculated by evaluating all of the ways receptors (i.e., USN Personnel) might be exposed to COPCs in the environment. For this SRE, the approach for evaluating risks associated with exposure to COPCs in tap water was more complicated than for other, more typical sites. At a typical site, the risks from tap water would be calculated by evaluating exposure to COPCs via:

- Ingestion of Tap Water (e.g., drinking, preparing food, cooking, brushing teeth, making ice)
- Inhalation of Vapors in Indoor Air Associated with Household Uses of Tap Water (e.g., showering, washing dishes, washing clothes, et cetera)
- Dermal Contact with Tap Water While Bathing¹⁸

In Naples, USN leadership implemented a Bottled Water Advisory (issued in July 2008 by CNREURAFSWA) due to wide-spread, low concentrations of VOCs and microorganisms that were detected in tap water, and currently requires landlords to provide potable bottled water from USN-approved sources at their residences. USN leadership also implemented the following changes to off-base rental-home lease clauses:

- If a residence's tap water supply is connected to a well, the landlord must provide verification that the well is legal according to Italian law. If it is not legal, the residence must be disconnected from the well and connected to the public drinking water system.
- Landlords must provide containerized water, approved by U.S. Army Veterinary Command (VETCOM), for drinking, preparing food, cooking, brushing teeth, making ice, and for pets.
- Landlords are required to clean and disinfect water holding tanks and associated plumbing every six months.

¹⁸Dermal contact with tap water while bathing or showering was not evaluated in this SRE because the USEPA does not include this exposure pathway in the development of the RSLs.

- Landlords are required to authorize the tenant to allow the USN, at any given time, to conduct necessary testing to verify the quality of the water at the residence, to include sampling of the soil and the air located around the residence.

These actions effectively minimized the exposure to COPCs in tap water via ingestion of tap water, but did not eliminate risks related to the inhalation pathway (e.g., exposure to COPCs in the tap water from bathing or showering¹⁹). There was no guarantee that the Bottled Water Advisory would be followed by every person and therefore, this action did not eliminate risks for those who were not drinking bottled water or risks related to the inhalation pathway (e.g., exposure to COPCs in the tap water from bathing or showering). Consequently, the risks in this SRE were calculated for two different exposure scenarios (for all media):

- **The Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure Scenario** – Risks were calculated based on exposure to COPCs in tap water, soil, and soil gas assuming that tap water was used for drinking, cooking, brushing teeth, and making ice. This scenario assumed that residents were not using bottled water, and were exposed to COPCs in their tap water through ingestion and inhalation of VOCs that could be released from the water.
- **The Tap Water (via Inhalation-Only), Soil, and Soil Gas Exposure Scenario** – Risks were calculated based on exposure to COPCs in tap water, soil, and soil gas assuming that tap water was not used for drinking, cooking, brushing teeth, and making ice. This scenario assumed that residents were using bottled water (as per the Advisory) and were not exposed to COPCs in tap water through ingestion²⁰.

4.1 Exposure Point Concentrations

The objective of this SRE was to evaluate the potential risks to the RME individuals. An RME individual is the “highest exposure that is reasonably expected to occur at the site” (USEPA, 1989). Because in most cases only one sample was collected for tap water, soil, and soil gas at each residence, no statistical analyses could be performed on these data. Therefore, detected concentrations were used as the RME EPCs for calculating the risks. At residences where multiple samples were collected for each medium, the maximum detected concentration was used as the RME EPC²¹. Nondetected results were not included in the risk calculations for tap water, soil, and soil gas. The analytical data used to develop the EPCs for tap water, soil, and soil gas are presented in ETSA Reports (Tetra Tech, 2008 and Tetra Tech, 2010b).

Unlike tap water, soil, and soil gas samples that were only collected one time, numerous ambient air samples were collected during the year-long ambient air sampling and monitoring program. Consequently, RME EPCs for ambient air were determined by calculating the 95% upper confidence limit (UCL) on the arithmetic mean (average) concentration for all samples collected in each study area.

¹⁹If VOCs are present in tap water they can volatilize into the indoor air during bathing and/or showering and then be inhaled, which results in a complete inhalation exposure pathway.

²⁰Although microorganisms are not of concern via the inhalation pathway, they were evaluated in comparison to USMCLs for the Tap Water via Inhalation-Only pathway to address the potential concern of incidental ingestion during showering and/or bathing, especially for infants and young children.

²¹For Phase II, active (i.e., SUMMA canister) sub-slab or near-slab soil gas samples were collected instead of the passive (i.e., Gore-Sorber®) sampling method that was used in Phase I. At residences sampled with both passive and active methods, only

Ambient air samples collected from residences in the study areas and U.S. Government-related facilities (i.e., not associated with the ambient air monitoring stations) were also included in the calculations. The 95% UCL on the logarithmic mean concentration (calculated using the H-statistic via the Land method) was used as the EPC if the data appeared to be lognormally distributed (5% significance level), and the 95% UCL on the arithmetic mean was used if the data appeared to be normally distributed (5% significance level). If the distribution could not be determined (i.e., the data were neither normally nor lognormally distributed), the 95% UCL on the arithmetic mean was used as the EPC, which is typically a reasonable assumption for data sets with over 30 data points because they tend to approximate a normal distribution. The maximum detected concentration was used if the 95% UCL on the logarithmic mean concentration or 95% UCL on the arithmetic mean concentration exceeded the maximum detected concentration. Nondetects were included in the statistical calculations using a surrogate value of one-half of the detection limit. Prior to performing the statistical analysis on the ambient air data, the data were pre-processed as described below:

- Field duplicate results were averaged based on the following decision rules:
 - If both results were detected, then the average concentration was calculated.
 - If one result was detected and the other result was not detected, then the detected result was used as the concentration for the sample.
 - If both results were not detected, then the lower of the detection limits was used as the quantitation limit for the sample.
- In instances where a COPC's result was reported by the laboratory using different analytical methods, only one result was retained in the analytical database based on the following decision rules:
 - If both results were detected, then the higher of the two results was used as the concentration for the sample.
 - If one result was detected and the other result was not detected, then the detected result was used as the concentration for the sample.
 - If both results were not detected, then the lower of the detection limits was used as the quantitation limit for the sample.

The statistical analysis and EPCs for ambient air data for each study area are presented in Appendix C.

4.2 Methodology for Calculating Risks

Analytical data from tap water, soil, soil gas, and ambient air samples were compared to RSLs, and constituent-specific CEFs and NCEF were calculated using the following equations:

the active soil gas results were included in the calculation for the SRE because these results are quantitative and are considered more reliable than the results obtained from the passive sampling method.

Tap Water	Soil	Soil Gas²²	Ambient Air
$EF = \frac{C_{Tap\ Water}}{Screening\ Criterion}$	$EF = \frac{C_{Soil}}{Screening\ Criterion}$	$EF = \frac{C_{Soil\ Gas}}{Screening\ Criterion}$	$EF = \frac{C_{Ambient\ Air}}{Screening\ Criterion}$

where:

Parameter	Description
TAP WATER	
$C_{Tap\ Water}$	Maximum detected concentration in the tap water samples collected from the residence
Screening Criterion	USEPA Residential-Based RSLs for tap water, calculated based on a carcinogenic risk of 1E-06 and/or a hazard quotient (HQ) of 1 – assuming a 30-year exposure duration USMCLs
SOIL	
C_{Soil}	Maximum detected concentration in the soil samples collected from the residence
Screening Criterion	USEPA Residential-Based RSLs for soil, calculated based on a carcinogenic risk of 1E-06 and/or an HQ of 1 – assuming a 30-year exposure duration
SOIL GAS	
$C_{Soil\ Gas}$	Maximum detected concentration in the soil gas samples collected from the residence ²³
α	Default USEPA VAFs were used to predict indoor air concentrations based on soil gas concentrations. For sub-slab and near-slab soil gas samples collected from less than or equal to five feet below the foundation level, a default attenuation factor of 0.1 was used in the calculations ²⁴ .
Screening Criterion	USEPA Residential-Based RSLs for air, calculated based on a carcinogenic risk of 1E-06 and/or a Hazard Quotient (HQ) of 1 – assuming a 30-year exposure duration
AMBIENT AIR	
$C_{Ambient\ Air}$	RME EPC (see Section 4.1). USEPA Residential-Based RSLs for air, calculated based on a carcinogenic risk of 1E-06 and/or a HQ of 1 – assuming a 30-year exposure duration
Screening Criterion	NAAQS A comparison of ambient air data from Naples to data from major U.S. cities was performed in order to provide context for evaluating the results.

A CEF or NCEF of one indicates that exposure to tap water, soil, soil gas, and/or ambient air could potentially result in a cumulative screening cancer risk of 1E-06 and a screening hazard index (HI) of 1, respectively.

Three separate risk calculations were performed (described below) for the SRE and were included in the letters provided to residents documenting the results of samples that were collected from their residence. However, only the results of the incremental risk calculations are presented and discussed in this SRE:

- Total Screening Risk – The risk for all COPCs (background and incremental)

²² Soil gas results are not directly comparable to ambient air USEPA RSLs. The soil gas results must be multiplied by an attenuation factor, which results in a predicted indoor air concentration that can be compared directly to USEPA RSLs.

²³For Phase II, active (i.e., SUMMA canister) sub-slab or near-slab soil gas samples were collected instead of the passive (i.e., Gore-Sorber®) sampling method that was used in Phase I. In instances where a residence was sampled using both passive and active methods, only the active soil gas results were used in the SRE because the results are considered more reliable than the results obtained from the passive sampling method.

²⁴A VAF of 0.1 was applied in all instances to evaluate soil gas, with the exception of multi-story residences that had subsurface ventilated garages or apartment-type dwellings where the resident lived above the ground-floor of the structure (i.e., the resident lived on the second floor or higher, assuming that the first floor was the ground floor of the building). In these instances a multi-story attenuation factor, assessed and supplied by Tetra Tech NUS, was applied as described in Appendix B.

- Background Screening Risk – The risk for COPCs that are naturally occurring in the environment (i.e., inorganic elements)
 - For soil, Naples-specific background chemical concentrations for inorganics were identified in *Background and Baseline Concentration Values of Elements Harmful to Human Health in the Volcanic Soils of the Metropolitan and Provincial Areas of Napoli (Italy)* (Cicchella, Domencio et al, 2005). Table 4-1 summarizes the background soil inorganic constituent concentrations from Naples, Italy. Figure 4-1 presents a summary of the comparison of arsenic concentrations in soil to the arsenic RSL throughout the nine study areas. As is evident from this figure, concentrations of arsenic exceeded RSLs at all soil sampling locations. Since the concentrations of arsenic are naturally occurring and are likely associated with volcanic activity in the region, inorganic COPCs with concentrations that were less than or equal to their corresponding background concentration were included in the background and total risk calculations, but were not included in the incremental risk calculations presented in this report.
 - For soil gas, no suitable background concentrations could be located in the scientific literature. Therefore, there are no background risks for soil gas. See Appendix D for a detailed evaluation of soil gas and potential contributions from ambient air sources.
 - For tap water, no suitable background concentrations could be located in the scientific literature. However, the Phase I tap water data indicated that inorganics (with the exception of arsenic, lead, copper, and thallium) were not detected at concentrations greater than RSLs or USMCLs (Tetra Tech, 2010b). An analysis of the arsenic concentrations in tap water samples was performed in December 2008 (Tetra Tech, 2008). This analysis indicated that arsenic was detected in all tap water samples at concentrations that exceeded the RSL. In addition, there did not appear to be a significant difference in arsenic concentrations between public tap water supplies and private well water supplies. This information, coupled with the regional geology (i.e., volcanic soils and high concentrations of arsenic in soil), indicated that arsenic in tap water was representative of natural background. Figure 4-2 presents a summary of a comparison of concentrations of arsenic in tap water to RSLs and USMCLs throughout the nine study areas. As is evident from this figure, elevated concentrations of arsenic are present throughout the Naples area of the Campania Region and the distribution is consistent with background. Lead, copper, and thallium were the only inorganics included in the incremental risk calculations because it was determined that tap water concentrations were not representative of background concentrations. Concentrations of all other inorganics, including arsenic, were considered representative of background concentrations and, therefore, were included in the total risk and background risk calculations only.
 - For ambient air, no suitable background concentrations for the Campania Region could be located in the scientific literature. Therefore, the 95% UCL on the mean concentration from data obtained for six U.S. cities (i.e., San Diego, California; Los Angeles, California; Seattle, Washington; Houston, Texas; Midlothian, Texas; and Washington DC) from the USEPA’s

2007 Air Toxics Database (USEPA, 2007a) were used to represent typical urban air²⁵. Table 4-2 compares the ambient air EPCs (for constituents detected in at least one sample) from each of the study areas to the EPCs from the USEPA's 2007 Air Toxics Database. Ambient air data that were obtained from the USEPA's 2007 Air Toxics Database were used in the SRE to put the ambient air concentrations obtained from the PHE into context for USN Personnel with respect to ambient air concentrations from urban cities in the U.S. However, the lack of Italy-specific background air concentrations from urban cities was a significant data gap for the SRE (see Section 5.2.5).

- Incremental Risk – Incremental risks were, in most cases, calculated by subtracting the background risks (i.e., risks for COPCs that are naturally occurring in the environment) from the total risks. Risk management decisions will be based on incremental risks.
 - For ambient air, incremental risks could not be calculated because background concentrations were not available from the Campania Region.
 - For soil gas, COPCs detected in soil gas were classified into the following three groups so that the risks could be calculated appropriately. For detailed information regarding the approach for classifying COPCs detected in soil gas, see *Technical Memorandum: Identification of Chemicals in Soil Gas That May be Associated with Vapor Intrusion*, which is presented in Appendix D of this volume (and appendix C.2 of the May 2010 QAPP).
 - Non-VI COPCs – COPCs associated with above-ground contaminant sources (i.e., ambient air) and not with subsurface VI. Risks for these COPCs were calculated using ambient air results at all residences. The following COPCs were identified as Non-VI COPCs: 1,2-dibromo-3-chloropropane, 1,2-dibromomethane, 1,2-dichloroethane, acrolein, and chloromethane.
 - Localized VI COPCs – COPCs potentially associated with a subsurface VI source within a specific geographical area. Most COPCs fall into this category because subsurface VI is commonly associated with a localized release. This group also includes COPCs for which the results were inconclusive. Risks for these COPCs were calculated using soil gas results at the residence if the soil gas concentration was greater than the 95th percentile ambient air concentration calculated based on the PHE's year-long ambient air sampling and monitoring program. If the soil gas concentration was less than or equal to the 95th percentile ambient air concentration calculated based on the PHE's year-long ambient air sampling and monitoring program, then it was concluded that the COPC was associated with ambient air and risks were calculated using the ambient air concentration (see Appendix D for more detailed information). The following COPCs were identified as Localized VI COPCs: 1,1,1,2-tetrachloroethane, 1,1,2,2-tetrachloroethane, 1,2-dichloropropane, 1,3-butadiene, 1,4-dichlorobenzene, acrylonitrile, bromoform, benzene, carbon tetrachloride, chloroform, ethylbenzene, hexane, hexachlorobutadiene, and methyl-tert-butyl ether.

²⁵ Refer to Section 4.1 for explanation on the development of EPCs.

- Global VI COPCs – COPCs associated with a presumed subsurface VI source at all residences regardless of the concentration measured in ambient air during the PHE (see Appendix D for more detailed information). To be classified as a Global VI COPC either there had to be compelling evidence to indicate that subsurface VI is a study-wide issue or the COPCs had to be degradation products of COPCs that were determined to be Global VI COPCs. Risks for these COPCs were calculated using soil gas results at all residences. The following COPCs were identified as Global VI COPCs: tetrachloroethene, trichloroethene, and vinyl chloride.

4.3 Risks Management Categories for Evaluating Incremental Screening Risks

This report characterizes the potential health risks associated with exposure at a residence for 30 years. This is a conservative assumption because typical tour lengths for USN Personnel stationed overseas typically range from three to six years. However, DoDDS personnel can remain at one location for 30 years or longer. Therefore, the USEPA's 30-year standard residential RSLs were used in order to ensure that the SRE was protective of RME individuals, which are DoDDS personnel.

4.3.1 Risk Management Criteria for Soil, Soil Gas, and Tap Water

The SRE results (incremental screening risks) associated with exposure to soil, soil gas, and tap water at a residence for 30 years were placed into one of two categories:

1. Acceptable Risks – The noncancer and cancer screening risks at this residence are considered Acceptable based on the PHE risk management criteria (presented below).
2. Unacceptable Risks – The noncancer and cancer screening risks at this residence are considered Unacceptable based on the PHE risk management criteria (presented below).

The PHE agreed-upon approach for evaluating the risks associated with exposure to THMs was to compare concentrations to the TTHM USMCL, rather than to the individual RSLs. THMs (i.e., bromodichloromethane, chloroform, bromoform, and dichlorobromomethane) are water-supply disinfectant byproducts, and are typically detected in municipal water supplies. For this evaluation, if the concentration of an individual THM in tap water exceeded the RSL, but was less than the TTHM USMCL, the risk was considered Acceptable.

PHE Risk Management Categories for Soil, Soil Gas, and Tap Water

Scenario	Criteria for Acceptable Incremental Risks	Criteria for Unacceptable Incremental Risks
Scenario 1 – Tap Water (via Inhalation-Only), Soil, and Soil Gas Exposure Scenario	Total CNCEF less than or equal to 1; and Total CCEF less than or equal to 10; and <i>Concentration less than or equal to USMCL (tap water). Applies only to fecal coliform and total coliforms.</i>	Total CNCEF greater than 1; or Total CCEF greater than 10; or <i>Concentration greater than the USMCL (tap water). Applies only to fecal coliform and total coliforms.</i>
Scenario 2 – Tap Water (via Ingestion+Inhalation), Soil, and Soil Gas Exposure Scenario	Total CNCEF less than or equal to 1; and Total CCEF less than or equal to 10; and Concentration less than or equal to USMCL (tap water). Applies to all COPCs.	Total CNCEF greater than 1; or Total CCEF greater than 10; or Concentration greater than the USMCL (tap water). Applies to all COPCs.
<p>Notes:</p> <p>NCEFs were calculated by dividing the maximum-detected concentrations by noncancer-based USEPA RSLs. CEFs were calculated by dividing the maximum-detected concentrations by cancer-based USEPA RSLs. The individual NCEFs and CEFs were summed to provide the CNCEF and CCEF, respectively. An NCEF of 1 corresponds to a screening HI of 1. A CEF of 1 corresponds to a cancer screening risk of 1E-06 (one in a million). A CEF of 10 corresponds to a cancer screening risk of 1E-05 (one in a 100,000). Total CNCEF is the result of summing the individual NCEFs for all COPCs for all media that were sampled at a residence. Total CCEF is the result of summing the individual CEFs for all COPCs for all media that were sampled at a residence.</p> <p>Scenario 1 – The tap water RSLs used to evaluate residences that DO NOT use tap water for drinking, cooking, brushing teeth, and making ice were based on inhalation during household uses (e.g., showering) of tap water only. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate.</p> <p>Scenario 2 – The tap water RSLs used to evaluate residences that DO use tap water for drinking, cooking, brushing teeth, and making ice were based on ingestion and inhalation during household uses (e.g., showering, washing clothes) of tap water. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate.</p> <p>The PHE agreed upon approach for this SRE was to evaluate the risks associated with exposure to THMs using the TTHM USMCL, rather than individual RSLs. THMs (i.e., bromodichloromethane, chloroform, bromoform, and dichlorobromomethane) are water-supply disinfectant byproducts, and are typically detected in municipal water supplies. For this evaluation, if the concentration of an individual THM in tap water exceeded the RSL, but was less than the TTHM USMCL, the risk was considered Acceptable.</p>		

4.3.2 Risk Management Criteria for Evaluating Ambient Air

The ambient air samples collected during the PHE reflect general ambient air quality that is impacted by emissions from point (e.g., factory) and non-point (e.g., automobile exhaust) sources (i.e., they were not specific to any industry or source). In the U.S., ambient air quality is regulated via the Clean Air Act (CAA, [U.S. Code, Title 42, Chapter 85]) and this framework was used to evaluate the ambient air results from Naples.

Under the CAA, the USEPA does not use a risk assessment “bright line” (e.g., a cancer risk of 1×10^{-6} to 1×10^{-4} or a hazard quotient greater than 1) to make risk management decisions based on the risks associated with generalized ambient air samples. The USEPA uses a technology-based and performance-based approach to significantly reduce emissions of air toxics from major sources of air pollution, followed by a risk-based approach to address any remaining, or residual risks. These are known as Maximum Achievable Control Technology [MACT] standards. MACT standards:

- consider cost and other non-air-quality factors,

- are based on emissions levels that are already being achieved by the better-controlled and lower-emitting sources in an industry group (i.e., similar industries),
- can be made more stringent by the USEPA when it makes economic, environmental, and public-health sense,
- are based on performance levels (40 CFR Part 63) where industry chooses technology to achieve a performance level that is practicable and cost effective , and
- consider residual risk. Residual risk is evaluated by the USEPA based on residual concentrations of hazardous air pollutants (HAPs) that are emitted to the atmosphere.

The CAA requires a residual risk standard for any source that is emitting a cancer-causing pollutant that poses an added risk of more than 1×10^{-6} to the most exposed receptor, while taking into consideration costs, energy, safety and other relevant factors. HAPs information is used to direct research into new areas where technologies can be developed to improve MACT standards, and consequently reduce risks associated with HAPs.

The cancer and noncancer risks associated with generalized ambient air sampling results are typically used by the USEPA to:

1. identify the chemicals that are responsible for the majority of the risks in ambient air; and
2. identify the major point and non-point sources of those chemicals.

This information is used to help focus research and development so that new pollution control technologies or changes in processes can be used to significantly reduce emissions of these chemicals through the permitting process. In other words, the USEPA recognizes that there will be cancer and noncancer risks associated with emissions from point and non-point sources, but it implements risk management actions at the source (e.g., stack or pipe) rather than at the point of exposure (i.e., the general air we breathe) because it is more feasible/practicable to reduce overall risks at the source or point of release rather than after a chemical has entered the atmosphere.

Italian authorities are responsible for the regulation of Italian air quality standards. The Navy will provide the Italian authorities with the air monitoring results.

4.4 Phase II Incremental Risk Summary for U.S. Leased Residences Located on the Italian Economy

The purpose of this section is to summarize the media and COPCs responsible for the majority of the incremental risks, using the data collected during Phase II of the SRE, and also identify trends that have been observed with regards to regional risks based on the Phase II data. Detailed risk results that utilize Phase I and Phase II data are presented in Appendix F.

This section presents general conclusions about the potential health risks associated with living in the Campania Region based solely on the results of Phase II of the SRE. These conclusions and any future conclusions, summaries, additional evaluations, and risk management decisions should consider/incorporate the limitations of the PHE risk assessment methodology used, the conservative assumptions incorporated into the SRE (e.g., assumption that a resident lives at a location for 30 years), and the unique conditions/limitations under which the PHE was performed.

4.4.1 Regional Summary of Incremental Risks for Phase II Residences

Two hundred and nine (209) residences were sampled for tap water, soil, and soil gas during Phase II (although not all media were sampled at every residence). As discussed in the introduction to this section, the risks in this SRE were calculated for two different scenarios for all media: (1) assuming tap water exposure via inhalation only and (2) assuming tap water exposure via ingestion and inhalation. Table 4-3 summarizes evaluation results by study area for all 209 residences sampled during Phase II. Table F-2 in Appendix F presents detailed risk information for each residence that was sampled during all PHE Sampling Events. Tables 4-4 through 4-12 summarize the information presented on Table 4-3 by presenting the number of residences with Unacceptable risks, the ranges of total CNCEFs and CCEFs, and the media and constituents responsible for the majority of the risks for each study area.

Twenty-two percent (46 of 209) of the residences sampled during Phase II had Unacceptable risks based on the tap water (inhalation-only), soil, and soil gas scenario. Forty-two percent (88 of 209) of the residences sampled during Phase II had Unacceptable risks based on the tap water (ingestion+inhalation), soil, and soil gas scenario. The box below summarizes the number of residences with Unacceptable risks per study area.

**Number of Residences with Unacceptable Incremental Risks
Per Study Area Sampled During Phase II**

Scenario 1 – Incremental Risks Based on Tap Water (Inhalation-Only), Soil, and Soil Gas									
Study Area 1	Study Area 2	Study Area 3	Study Area 4	Study Area 5	Study Area 6	Study Area 7	Study Area 8	Study Area 9	All
5 of 30 (17%)	2 of 22 (9%)	0 of 14 (0%)	2 of 14 (14%)	10 of 33 (30%)	5 of 30 (17%)	4 of 24 (17%)	18 of 34 (53%)	0 of 8 (0%)	46 of 209 (22%)
Scenario 2 – Incremental Risks Based on Tap Water (Ingestion+Inhalation), Soil, and Soil Gas									
Study Area 1	Study Area 2	Study Area 3	Study Area 4	Study Area 5	Study Area 6	Study Area 7	Study Area 8	Study Area 9	All
8 of 30 (27%)	13 of 22 (59%)	1 of 14 (7%)	4 of 14 (29%)	15 of 33 (45%)	13 of 30 (43%)	9 of 24 (38%)	24 of 34 (71%)	1 of 8 (13%)	88 of 209 (42%)
Number of Residences Sampled That Obtained Their Water from a Private Well									
Study Area 1	Study Area 2	Study Area 3	Study Area 4	Study Area 5	Study Area 6	Study Area 7	Study Area 8	Study Area 9	All
0 of 30 (0%)	0 of 22 (0%)	0 of 14 (0%)	0 of 14 (0%)	5 of 33 (15%)	1 of 30 (3%)	0 of 24 (0%)	7 of 34 (21%)	0 of 8 (0%)	13 of 209 (6%)

As shown on Figures 4-3 and 4-4, the residences with Unacceptable risks are located throughout the study areas, with the highest number of Unacceptable risks observed in Study Area 8. This result was expected. Prior to commencement of the PHE, Italian maps and anecdotal information regarding historical waste disposal practices in agricultural areas (such as Study Areas 5, 6, 7, 8, and 9) presented in the press/literature, indicated that Study Area 8 would likely be one of the study areas with a large number of Unacceptable risks. In addition, many of the residences in Study Area 8 obtained their tap water from private wells which may be more susceptible to contamination from localized dumping of industrial/chemical waste than public water supply systems (seven of the residences with Unacceptable risks obtained their tap water from a private well). This was consistent with the results of Phase I of the

SRE where 30 of the 36 (83%) residences that obtained their tap water from a private well had Unacceptable risks whereas 18 of the 94 (19%) residences that obtained their tap water from a public source had Unacceptable risks (PIONEER, 2009). The results of Phase II were consistent with Phase I results, as 13 of the 13 residences (100%) in Phase II that obtained their tap water from a private well had Unacceptable risks. Study Areas 3 and 9 had the lowest percentage of Unacceptable risks but also had the fewest number of residences sampled; therefore it was not possible to reach any conclusion regarding the significance of these findings. The number and frequency of Unacceptable risks for Study Areas 1 and 2 were unexpected because these areas are densely populated and do not have expansive agricultural areas or open space which could readily be used for illegal waste disposal activities. In addition, all of the residences in these study areas obtained their tap water from a public source.

Residences with Acceptable risks and Unacceptable risks were distributed throughout the study areas and often were located very close to each other. In other words, the residences with Unacceptable risks were generally randomly distributed (with some exceptions) within the study areas (see Figures 4-3 and 4-4). Exceptions to this general observation are identified below:

- **Scenario 1 – Risks Based on Tap Water (Inhalation-Only), Soil, and Soil Gas (Figure 4-3)**
 - There was a cluster of Unacceptable residences in Study Area 8 within the New Lease Suspension Zone (NLSZ).
 - Unacceptable residences located outside of Study Area 8 were often found in clusters of two or three.
- **Scenario 2 – Risks Based on Tap Water (Ingestion+Inhalation), Soil, and Soil Gas (Figure 4-4)**
 - There was a cluster of Unacceptable residences located in:
 - Study Area 2, near the U.S. Consulate,
 - Study Area 5, near the Lago Patria Receiver Site,
 - Study Area 6 near the Support Site, and
 - Study Area 8 within the NLSZ.

As summarized in the box presented below, the ranges of risks were highly variable and heterogeneous throughout the study areas and within the study areas. Because of the high degree of variability between the risks it was inappropriate to calculate an “average risk” or “upper-bound” risk for each study area or across all study areas. To demonstrate this point, the average total CCEF based on the tap water (inhalation-only), soil, and soil gas scenario for Study Area 5 was 11.6, which was Unacceptable based on the PHE risk management criteria. Based on the average total CCEF, one might conclude that the risks within this study area were Unacceptable; however, this would be incorrect because 23 of the 33 residences sampled had Acceptable risks (i.e., the total CCEFs for 23 of the 33 residences were less than 10).

Range of Incremental Risks Per Study Area for Residences Sampled During Phase II

4.4.1.1 Media Responsible for the Majority of the Incremental Risks in Phase II

The majority of the Unacceptable risks identified during Phase II sampling were associated with COPCs detected in tap water from private wells and soil gas collected from under or within 10 feet of the residence. None of the COPCs detected in soil samples collected from residences during Phase II posed an Unacceptable risk. In fact, soil sampling was discontinued midway through Phase II because results from Phase I samples and Phase II samples indicated that soil contamination did not pose a significant human health risk. The results of the year-long ambient air sampling and monitoring program that was conducted as part of the PHE indicated that ambient air in the Campania Region was similar to typical ambient air from cities in the U.S. when cumulative risks were calculated using only those constituents that had corresponding values in both data sets. The risks associated with tap water and soil gas are summarized below.

- **Scenario 1 – Tap Water Risks Based on The Inhalation-Only**
 - Tap Water from a Public Source: Seven (7) of the 193 residences (4%) sampled for tap water obtained from a public source during Phase II had Unacceptable risks due to concentrations of COPCs in tap water (see Figure 4-5). All seven of these Unacceptable risks were due to microorganisms in tap water and were distributed randomly throughout the study areas.

- Tap Water from a Private Well: Twelve (12) of the 13 residences (92%) sampled during Phase II that obtained their tap water from a private well²⁶ or unknown source had Unacceptable risks due to concentrations of COPCs in tap water (see Figure 4-5). Six of the 12 residences had Unacceptable concentrations of chemicals in tap water and 11 of the 12 residences had Unacceptable risks due to microorganisms in tap water. Some of the residences with microorganisms detected in tap water were co-located with the Unacceptable chemical risks; therefore, the total number of residences with Unacceptable microorganism results plus the total number of residences with chemical results does not equal 12. These residences were primarily located in Study Areas 5 and 8.
- **Scenario 2 – Tap Water Risks Based on The (Ingestion+Inhalation)**
 - Tap Water from a Public Source: Fifty-one (51) of the 193 residences (26%) sampled for tap water obtained from a public source during Phase II had Unacceptable risks due to concentrations of COPCs in tap water (see Figure 4-6). Forty-five (45) of the 51 residences had Unacceptable concentrations of chemicals in tap water and seven of the 51 residences had Unacceptable risks due to microorganisms in tap water. Some of the residences with microorganisms detected in tap water were co-located with the Unacceptable chemical risks; therefore, the total number of residences with Unacceptable microorganism results plus the total number of residences with chemical results does not equal 51. These residences were primarily located in Study Areas 2, 6, 7, and 8, with the remainder randomly distributed within the other Study Areas.
 - Tap Water from a Private Well: Thirteen (13) of the 13 residences (100%) sampled during Phase II that obtained their tap water from a private well or unknown source had Unacceptable risks due to concentrations of COPCs in tap water (see Figure 4-6). Thirteen (13) of the 13 residences had Unacceptable concentrations of chemicals in tap water and 11 of the 13 residences had Unacceptable risks due to microorganisms in tap water. Some of the residences with microorganisms detected in tap water were co-located with the Unacceptable chemical risks; therefore, the total number of residences with Unacceptable microorganism results plus the total number of residences with chemical results does not equal 13. These residences are primarily located in Study Areas 5 and 8.
- **Soil**
 - None (0) of the 80 residences (0%) that were sampled for soil during Phase II had Unacceptable risks based solely on COPCs in soil.
- **Soil Gas**
 - Thirty-two (32) of the 175 residences (18%) that were sampled for soil gas during Phase II had Unacceptable risks based solely on COPCs in soil gas (see Figure 4-7). Clusters of residences with Unacceptable risks associated solely with COPCs detected in soil gas were observed primarily in Study Areas 1, 5, 6, and 8.
- **Ambient Air**

²⁶The residences that obtained their tap water from a private well were located in Study Area 5 (seven residences), Study Area 6 (one residence), and Study Area 8 (seven residences).

- *Note: Incremental risks could not be calculated for ambient air because background concentrations were not available for Naples, Italy (see Section 4.2). Therefore, only total risks could be calculated. The following information is based on total risks. The CCEFs and CNCEFs for the nine study areas in Naples ranged from 495 to 846 and 75 to 253, respectively, which exceeded the cumulative cancer and noncancer risks calculated using concentrations representative of typical urban air in the U.S. (160 and 33, respectively) (USEPA, 2007a). However, the risks associated with exposure to ambient air in Naples are not directly comparable to the risks associated with exposure to ambient air in the U.S. because some of the constituents detected in the nine study areas did not have corresponding values in the USEPA’s 2007 Air Toxics Database. When those constituents (e.g., 1,2-dibromo-3-chloropropane, which was responsible for, on average, 80% of the cancer risks in each study area) were not included in the calculations of the cumulative EFs, the CCEFs for the nine study areas were less than the typical urban air in the U.S. in all but one study area (i.e., Study Area 8) (see Table 4-21). The CNCEFs did not change appreciably (i.e., the difference was less than one percent) when the cumulative EFs were recalculated using only constituents that had corresponding values in the USEPA’s 2007 Air Toxics Database, primarily because acrolein (the constituent that contributed the majority of the CNCEF in the nine study areas) had values in both data sets (see Table 4-21). Because some constituents (including 1,2-dibromo-3-chloropropane) did not have corresponding values in the USEPA’s 2007 Air Toxics Database, it was not possible to determine whether or not the cumulative ambient air risks in the Campania Region exceeded the risks from typical urban air in the U.S.*

4.4.1.2 COPCs Responsible for the Majority of the Incremental Risks in Phase II

The following box identifies COPCs that exceeded RSLs and/or USMCLs (USMCLs apply to tap water only) in tap water, soil, soil gas, and/or ambient air during Phase II:

COPCs Based on All Residences Sampled During Phase II

Tap Water ¹	Soil	Soil Gas ²	Ambient Air
TAP WATER (PRIVATE WELLS) RSLs Exceedances: Carbon Tetrachloride Copper Fluoride Nitrate Tetrachloroethene Total cPAHS (BaP TEQs) Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium USMCL Exceedances: Fecal Coliform Nitrate Tetrachloroethene Total Coliforms	RSLs Exceedances: Total cPAHS (BaP TEQs)	RSLs Exceedances: 1,1,1,2-Tetrachloroethane 1,1,2,2-Tetrachloroethane 1,2-Dichloropropane 1,3-Butadiene 1,4-Dichlorobenzene Acrylonitrile Benzene Bromoform Carbon Tetrachloride Chloroform Ethylbenzene Hexachlorobutadiene Hexane Methyl tert-Butyl Ether Tetrachloroethene Trichloroethene Vinyl Chloride	RSLs Exceedances: 1,1,1,2-Tetrachloroethane 1,1,2,2-Tetrachloroethane 1,2-Dibromo-3-Chloropropane 1,2-Dibromoethane 1,2-Dichloroethane 1,2-Dichloropropane 1,3-Butadiene 1,4-Dichlorobenzene Acetaldehyde Acrolein Acrylonitrile Arsenic Benzene Bromodichloromethane Carbon Tetrachloride Chloroform Cobalt

COPCs Based on All Residences Sampled During Phase II

Tap Water ¹	Soil	Soil Gas ²	Ambient Air
TAP WATER (PUBLIC SOURCE) RSLs Exceedances: Copper Fluoride Lead Nitrate Tetrachloroethene Total cPAHS (BaP TEQs) Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium USMCL Exceedances: Fecal Coliform Nitrate Total cPAHS (BaP TEQs) Total Coliforms			Dibromochloromethane Dieldrin Ethylbenzene Formaldehyde Hexachlorobutadiene Hexane Naphthalene Tetrachloroethene Total cPAHS (BaP TEQs) Total Dioxin/Furans (2,3,7,8-TCDD TEQs)
Notes: ¹ Tap water COPCs include constituents with concentrations in tap water greater than RSLs and/or USMCLs calculated assuming tap water exposure via: (1) inhalation only and (2) ingestion and inhalation. ² Soil gas COPCs include those that were identified as VI COPCs in the <i>Technical Memorandum: Identification of Chemicals in Soil Gas that may be Associated with Vapor Intrusion</i> , which is presented in Appendix D of this volume.			

Not all of the COPCs contributed significantly to the regional risks calculated as part of Phase II of the SRE. Some of the COPCs infrequently and/or only slightly exceeded their RSLs and/or USMCLs, which indicated that the risks were limited to a few residences and were not indicative of a larger study-area-wide risk or region-wide risk. This should not be construed to imply that some risks are less important or more important than others. All exceedances of RSLs/USMCLs should be treated with concern and addressed accordingly. Appendix H presents U.S. Agency for Toxic Substances and Disease Registry Chemical Fact Sheets (ToxFAQs™), where available, for each COPC. Each fact sheet serves as a quick and easy-to-understand guide that discusses exposure to hazardous substances found around hazardous waste sites and the effects of exposure on human health.

In a large regional study such as the PHE, a primary focus is on area-wide or region-wide risks because they are more likely to represent an effect on most of the population (e.g., USN Personnel who may work, play and/or live at different facilities in the study areas at different times). Therefore, the COPCs presented in the previous box were evaluated to identify constituents of concern (COCs) from (1) COPCs that were potentially an area-wide or region-wide concern and (2) COPCs that posed an Unacceptable risk in a single or multiple media (i.e., even if the risks for other COPCs were not considered). Solely for the purposes of focusing the following discussion, COCs in tap water, soil, soil gas, and ambient air²⁷ were identified from Tables 4-13 through 4-18 as follows:

1. If greater than 10% of the total number of residences sampled had concentrations greater than the RSL

²⁷For ambient air, COCs were identified as COPCs with an RME EPC that was greater than the EPC based on USEPA's 2007 Air Toxics Database AND where the CEF was greater than 10 and/or NCEF was greater than one and/or the EPC was greater than the NAAQS (see Table 4-20).

- If greater than 2.5% of the total number of residences sampled had concentrations that were greater than 10 times their RSL and/or greater than their USMCL (tap water only) and/or NAAQS (air only)

Based on the criteria presented above, the following box presents the COCs that were responsible for the majority of study-area-wide and region-wide risks.

COCs Based on All Residences Sampled During Phase II

Tap Water ¹	Soil	Soil Gas ²	Ambient Air
TAP WATER (PRIVATE WELLS) Carbon Tetrachloride Copper Fecal Coliform Fluoride Nitrate Tetrachloroethene Total cPAHS (BaP TEQs) Total Coliforms Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium TAP WATER (PUBLIC SOURCE) Lead Tetrachloroethene Total Coliforms Total Dioxin/Furans (2,3,7,8-TCDD TEQs) Uranium	Total cPAHS (BaP TEQs)	Benzene Chloroform Ethylbenzene Tetrachloroethene	1,2-Dibromo-3-Chloropropane 1,2-Dichloropropane Acetaldehyde Acrolein Arsenic Benzene Hexane Tetrachloroethene Total Dioxin/Furans (2,3,7,8-TCDD TEQs)
Notes: ¹ Tap water COCs include constituents with concentrations in tap water greater than RSLs and/or USMCLs calculated assuming tap water exposure via: (1) inhalation only and (2) ingestion and inhalation. ² Soil gas COCs include those that were identified as VI COCs, as per the Technical memorandum: <i>Identification of Chemicals in Soil Gas that may be Associated with Vapor Intrusion</i> , which is presented in Appendix D of this volume.			

4.4.1.3 COCs in Tap Water Responsible for the Majority of the Incremental Risks in Phase II

Carbon Tetrachloride: If tap water was ingested (i.e., tap water risks are based on the ingestion+inhalation scenario), then carbon tetrachloride in tap water was responsible for Unacceptable risks at one of 13 residences (8%) that obtained their tap water from a private well. As presented on Figure 4-9, the Unacceptable result was observed at a residence that obtained their tap water from a private well located in Study Area 6 (see Table 4-16).

Copper: Copper is not of concern to human health via inhalation of tap water because it is not volatile; therefore, there were no locations with Unacceptable risks associated with inhalation of copper from tap water. However, if tap water was ingested, then copper in tap water would be responsible for Unacceptable risks at one of 13 residences (8%) that obtained their tap water from a private well. As presented on Table 4-16 and Figure 4-10, no regional pattern was apparent for copper.

Fecal coliform: Fecal coliform is not volatile but was evaluated under the tap water inhalation-only and tap water ingestion+inhalation scenarios because if tap water was used only for showering or bathing,

people may incidentally ingest fecal coliform which are of concern to human health. Fecal coliform in tap water was responsible for Unacceptable risks at one of 13 residences (8%) – this concentration exceeded the USMCL. As presented on Figure 4-11, this residence obtained tap water from a private well located in Study Area 5 (see Table 4-16).

Fluoride: Fluoride is not of concern to human health via inhalation of tap water because it is not volatile; therefore, there were no locations with Unacceptable risks associated with inhalation of fluoride from tap water. However, if tap water was ingested, then fluoride in tap water would be responsible for Unacceptable risks at one of 13 residences (8%) that obtained their tap water from a private well. As presented on Table 4-16 and Figure 4-12, no regional pattern was apparent for fluoride.

Lead: Lead is not of concern to human health via inhalation of tap water because it is not volatile; therefore, there were no locations with Unacceptable risks associated with inhalation of lead from tap water. However, if tap water was ingested, then lead in tap water would be responsible for Unacceptable risks at nine of 193 residences (5%) that obtained their tap water from a public source. As presented on Table 4-15 and Figure 4-13, no regional pattern was apparent for lead. Please note that the risk-based screening criterion used in this SRE (i.e., 20 ug/L) was developed using the USEPA’s IEUBK Model (USEPA, 2007b). This is slightly higher than the USEPA’s tap water action level²⁸ for lead (i.e., 15 ug/L). For comparison purposes, when the USEPA’s tap water action level of 15 ug/L was compared to the tap water data, then lead was responsible for Unacceptable risks at 12 of 193 (6%) of residences that obtain their tap water from a public source.

Nitrate: Nitrate is not of concern to human health via inhalation of tap water because it is not volatile; therefore, there were no locations with Unacceptable risks associated with inhalation of nitrate from tap water. However, if tap water was ingested, then nitrate in tap water was detected at concentrations that exceeded the USMCL at 12 of 13 residences (92%) that obtained their tap water from a private well. As presented on Table 4-16 and Figure 4-14, these exceedances were most often observed in Study Areas 5 and 8, with a very limited number of exceedances in Study Areas 6 and 7.

Tetrachloroethene: If tap water was not ingested (i.e., tap water risks were based on the inhalation-only scenario), then tetrachloroethene in tap water was responsible for Unacceptable risks at six of 13 residences (46%) that obtained their tap water from a private well – the concentration at these locations also exceeded the USMCL. As presented on Figure 4-15, all of these Unacceptable results were observed in residences that obtained their tap water from private wells located in Study Areas 5 and 8 (see Table 4-14).

If tap water was ingested (i.e., tap water risks were based on the ingestion+inhalation scenario), then tetrachloroethene in tap water was responsible for Unacceptable risks at seven of 13 residences (54%) that obtained their tap water from a private well – the concentration at six of these locations also exceeded the USMCL. As presented on Figure 4-16 all of these Unacceptable results were observed at residences that

²⁸Lead is regulated by the Lead and Copper Rule in the U.S. that requires water system managers to control the corrosiveness of their water. If more than 10% of tap water samples exceed the action level, water systems must take additional steps (56 Federal Register [FR] 26460 – 26564, June 7, 1991). Technical Amendments: 56 FR 32112, July 15, 1991; 57 FR 28785, June 29, 1992; 59 FR 33860, June 30, 1994; and the Minor Revisions 65 FR 1950, January 12, 2000. www.epa.gov/safewater/leadcop.html

obtained their tap water from private wells located in Study Areas 5 and 8. In addition, tetrachloroethene in tap water was detected (i.e., 41 of 206 residences or 20%) at concentrations that exceeded the RSL but were below the PHE's risk management criteria for Unacceptable risk, regardless of the source of tap water. The majority of these exceedances were observed in residences that obtained their tap water from a public source located in Study Areas 1 and 2 (i.e., eight of 29 residences and 19 of 22 residences, respectively) (see Tables 4-15 and 4-16).

Total cPAHs (BaP TEQs): Total cPAHs (BaP TEQs) are not of concern to human health via inhalation of tap water because they are not volatile; therefore, there were no locations with Unacceptable risks associated with inhalation of total cPAHs (BaP TEQs) from tap water. If tap water was ingested, then total cPAHs (BaP TEQs) in tap water would be responsible for Unacceptable risks at one of seven residences (14%) that obtained their tap water from a private well. As presented on Table 4-16 and Figure 4-17, no regional pattern was apparent for total cPAHs (BaP TEQs).

Total Coliforms: Total coliforms are not volatile but were evaluated under the tap water inhalation-only and tap water ingestion+inhalation scenarios because if tap water was used only for showering or bathing, people may incidentally ingest total coliforms which are of concern to human health. Total coliforms in tap water were responsible for Unacceptable risks at 18 of 206 residences (9%), regardless of the source of tap water – these concentrations exceeded the USMCL. As presented on Figure 4-18, 11 of the 13 residences (85%) with Unacceptable risks that obtained their tap water from a private well were located in Study Areas 5, 6, and 8. Seven (7) of 193 residences (4%) with Unacceptable risks obtained their tap water from a public source located in Study Areas 2, 4, 5, 7, and 8 (see Tables 4-15 and 4-16).

Total Dioxins/Furans (2,3,7,8-TCDD TEQs): Total dioxins/furans (2,3,7,8-TCDD TEQs) are not of concern to human health via inhalation of tap water because they are not volatile; therefore, there were no locations with Unacceptable risks associated with inhalation of total dioxins/furans (2,3,7,8-TCDD TEQs) from tap water. If tap water was ingested, there were no locations with Unacceptable risks associated with total dioxins/furans (2,3,7,8-TCDD TEQs) in tap water, regardless of the source of tap water. However, as presented on Figure 4-19, total dioxins/furans (2,3,7,8-TCDD TEQs) were detected at concentrations that exceeded the RSL at 27 of 193 residences (14%) that obtained their tap water from a public source, but were below the PHE's risk management criteria for Unacceptable risk (see Table 4-15). Total dioxins/furans (2,3,7,8-TCDD TEQs) were detected at concentrations that exceeded the RSL at two of 13 residences (15%) that obtained their tap water from a private well, but were below the PHE's risk management criteria for Unacceptable risk (see Table 4-16).

Uranium: Uranium is not of concern to human health via inhalation of tap water because it is not volatile; therefore, there were no locations with Unacceptable risks associated with inhalation of uranium from tap water. If tap water was ingested (i.e., tap water risks were based on the ingestion+inhalation scenario), then uranium in tap water would be responsible for Unacceptable risks at three of 13 residences (23%) – none of these Unacceptable concentrations exceeded the USMCL. As presented on Figure 4-20, all of these Unacceptable results were observed in residences that obtained their tap water from private wells located in Study Areas 5 and 8. In addition, uranium in tap water was detected at concentrations that exceeded the RSL at 81 of 206 residences (39%) but below the PHE's risk management criteria for Unacceptable risk. The majority of these exceedances (i.e., 71 of 193 [37%]) were observed in residences

that obtained their tap water from a public source located across the study areas, which indicated that the uranium exceedances were associated with natural background concentrations rather than illicit disposal of radioactive waste (see Tables 4-15 and 4-16).

4.4.1.4 COCs in Soil Responsible for the Majority of the Risks in Phase II

Total cPAHs (BaP TEQs): Total cPAHs (BaP TEQs) in soil were responsible for Unacceptable risks at none (0) of the 80 residences that were sampled for soil. However, some concentrations of total cPAHs (BaP TEQs) in soil were detected at concentrations that exceeded the RSL but were below the PHE's risk management criteria for Unacceptable risk (see Figure 4-21 and Table 4-17).

4.4.1.5 COCs in Soil Gas Responsible for the Majority of the Risks in Phase II

Benzene: Benzene is a Localized VI COPC in soil gas (see Appendix D) and was responsible for Unacceptable risks at three of 175 residences (2%) that were sampled for soil gas. However, benzene in soil gas was detected at concentrations that exceeded the RSL at 20 of 175 residences (11%) but concentrations were below the PHE's risk management criteria for Unacceptable risk. As presented on Table 4-18 and Figure 4-22, the majority of these exceedances were observed in Study Area 8, with a limited number of exceedances in other study areas.

Chloroform: Chloroform is a Localized VI COPC in soil gas (see Appendix D) and was responsible for Unacceptable risks at eight of 175 residences (5%) that were sampled for soil gas. However, chloroform in soil gas was detected at concentrations that exceeded the RSL at 40 of 175 residences (23%) but concentrations were below the PHE's risk management criteria for Unacceptable risk. As presented on Table 4-18 and Figure 4-23, the exceedances were typically clustered within Study Areas 1, 5, 6, 7, and 8, which may indicate a potential subsurface source.

Ethylbenzene: Ethylbenzene is a Localized VI COPC in soil gas (see Appendix D) and was responsible for Unacceptable risks at one of 175 residences (1%) that were sampled for soil gas. However, ethylbenzene in soil gas was detected at concentrations that exceeded the RSL at 24 of 175 residences (14%) but concentrations were below the PHE's risk management criteria for Unacceptable risk. As presented on Table 4-18 and Figure 4-24, the majority of these exceedances were observed in Study Area 8, with a limited number of exceedances in other study areas. In addition, some of the ethylbenzene exceedances were co-located with benzene exceedances.

Tetrachloroethene: Tetrachloroethene is a Global VI COPC in soil gas (see Appendix D) and was responsible for Unacceptable risks at 15 of 175 residences (9%) that were sampled for soil gas. The Unacceptable results were primarily clustered in Study Area 5 (three residences), Study Area 6 (four residences), and Study Area 8 (six residences), which indicated potential subsurface sources in soil and/or groundwater. In addition, tetrachloroethene in soil gas was detected at concentrations that exceeded the RSL at 78 of 175 residences (45%) but concentrations were below the PHE's risk management criteria for Unacceptable risk. As presented on Table 4-18 and Figure 4-25, the exceedances were widespread, which were typically more indicative of an ambient air source, rather than potential subsurface source.

4.4.1.6 COCs in Ambient Air Responsible for the Majority of the Risks in Phase II in Comparison to Typical U.S. Urban Air

As shown on Table 4-21, the ambient air CCEF and CNCEFs for the nine study areas ranged from 495 to 846 and 75 to 253, respectively, when the calculations included all constituents detected in ambient air in the Campania Region. Both the cancer and noncancer risks from the Campania Region exceeded the risks calculated from the USEPA's 2007 Air Toxics Database (USEPA, 20007a) for typical U.S. urban air (i.e., CCEF of 160 and CNCEF of 33). However, when cumulative risks were calculated using only those constituents that had corresponding values in both data sets, the CCEF and CNCEF for the nine study areas ranged from 94 to 204 and 75 to 252, respectively (see Table 4-21).

For the purpose of focusing the following discussion on the COCs that contributed to the majority of the ambient air risk, Table 4-20 presents the nine COCs that had RME EPCs that: 1) resulted in a CEF greater than 10 or NCEF greater than one in at least one study area, and 2) were greater than the RME EPC from the USEPA's 2007 Air Toxics Database. A discussion of ambient air risks associated with these COCs, by study area, is presented in Appendix F. The key findings are presented in Table 4-19 and 4-20 include the following:

- 1,2-Dibromo-3-chloropropane contributed the majority of the CCEF (average of 80%) for the nine study areas. The COC-specific CEF ranged from 397 to 727. 1,2-Dibromo-3-chloropropane was not included in the USEPA's 2007 Air Toxics Database so the ambient air concentrations from the PHE could not be compared with typical urban ambient air from the U.S.
- Acrolein contributed the majority of the CNCEF (average of 95%) for the nine study areas. The maximum NCEF (247) calculated for Study Area 7 was greater than the NCEF calculated for acrolein in typical urban air in the USEPA's 2007 Air Toxics Database (29). Acrolein also contributed the majority of the NCEF for typical urban air in the U.S. (average of 89%).
- 1,2-Dichloropropane contributed an average of 3.5% to the cancer risk and 1.1% to the noncancer risk in the nine study areas.
- The six other COCs contributed an average of less than two percent each to the cumulative cancer and noncancer risk for the nine study areas.
 - EPCs for total dioxins/furans varied significantly among study areas. Study Areas 6, 8, and 9 were the only study areas where the COC-specific CEF exceeded 10.
 - Arsenic EPCs were less than the EPC in typical urban air in the USEPA's 2007 Air Toxics Database in all study areas except for Study Area 3 where the COC-specific CEF was 16. Slightly elevated arsenic concentrations in Study Area 3 could be associated with more volcanic activity in the area.
 - The maximum CEF for benzene was detected in Study Area 8 at a concentration of 68, which was approximately 10 times higher than the CEF for typical urban air in the U.S. (i.e., 5.2). The CEFs for benzene in the other eight study areas were less than 10.
- With the possible exception of total dioxins/furans in Study Areas 6, 8, and 9, no obvious trends were indicative of localized concentrations that might be associated with trash burning, trash dumping, or other point and non-point sources. Typically, there was not a significant difference in EPCs between study areas for the COCs, indicating that the concentrations represented typical urban air in the Campania Region.

- 1,2-Dibromoethane and formaldehyde together contributed to 65% of the CCEF in the USEPA's 2007 Air Toxics Database (USEPA, 2007a) but were not significant contributors to the ambient air risk in the nine study areas (6%).

Cumulative risks in the nine study areas exceeded the cumulative risks for typical urban air calculated from the USEPA's 2007 Air Toxics Database (USEPA, 2007a). However, because some constituents (including 1,2-dibromo-3-chloropropane, the major cancer risk driver in the Campania Region) did not have corresponding values in the USEPA's 2007 Air Toxics Database, it was not possible to determine whether or not the cumulative ambient air risks in the Campania Region would have exceeded the risks from typical urban air in the U.S. (see Table 4-21). The risk-driving COPCs for cancer risks based on the USEPA's 2007 Air Toxics Database (i.e., 1,2-dibromoethane and formaldehyde) together contributed to 65% of the typical urban air CCEF. These constituents were not significant contributors to cancer risks in the nine study areas. For a more complete summary of the year-long ambient air sampling and monitoring program, please see the *Ambient Air Quality and Meteorological Summary Report for the Period July 9, 2008 through July 8, 2009* (Tetra Tech, 2010a).

4.5 Incremental Risk Summary for Other Sampling Events

The Naples PHE Project Team increased the number of residences sampled in some study areas as information became available during Phase I and Phase II of the PHE. Each Sampling Event was performed as a separate component of the PHE. The purpose of this section is to present the risk summary for each of these events. Note: These data were not included in the regional discussion of risk that was presented in Section 4.4.

4.5.1 Incremental Risk Summary for Step-Out Sampling

During Phase I of the PHE, tap water results from some residences that obtained their tap water from private wells in Casal di Principe (Study Area 8) had Unacceptable concentrations of tetrachloroethene. These results indicated the potential for groundwater and/or soil contamination in this area. The USN was unable to obtain any information regarding the potential source(s) or the extent (i.e., the vertical or horizontal distribution) of tetrachloroethene in groundwater from Italian Regulatory Agencies. Consequently, a Step-Out Sampling Event was performed to identify other residences occupied by USN Personnel that may have been potentially impacted by the presumed groundwater contamination. Initially, this effort involved identifying and sampling residences occupied by USN Personnel located within 500 feet²⁹ (in all directions) of the initial residence with the Unacceptable concentration of tetrachloroethene in tap water from private wells. Based on the results of this effort (i.e., the 500-foot Step-Out Sampling Event), which indicated that all residences sampled also had Unacceptable risks associated with tetrachloroethene in groundwater, another expanded sampling event was conducted. This involved identifying and sampling residences occupied by USN Personnel located within 1,500 feet (in all

²⁹The 500-foot step-out was based on VI and other guidance documents that recommended additional investigation for areas within 100 feet of the edge of a known and documented subsurface contamination source. Lacking information on the size or characteristics of the vapor or presumed-to-be impacted groundwater, and the relative location of the residence with Unacceptable risk within the area, a Step-Out distance of 500 feet was used to err on the side of being protective and to demonstrate that residences within the 500-foot Step Out had an Acceptable risk.

directions) of residences that had Unacceptable concentrations of tetrachloroethene in tap water obtained from private wells.

In the U.S., it is common practice to utilize Step-Out sampling in environmental investigations to determine the extent of contamination in a geographic area where a contaminant source is documented and under investigation. This method selects sampling locations a specific distance (potentially in all directions) from the initial location where there is identified contamination with the goal of determining the extent of contamination. In the PHE, if there was contamination in the Step-Out samples attributable to the same constituent that was responsible for "triggering" the Step-Out Sampling Event, field personnel collected subsequent rounds of Step-Out samples further from the residence that triggered the Step Out, until sample results were Acceptable.

4.5.1.1 Incremental Risks Summary for the 500-Foot Step-Out Sampling Event

Seven residences sampled during the Phase I investigation had Unacceptable concentrations of tetrachloroethene in tap water that was obtained from private wells. However, only three of the residences, which were all located in Study Area 8 (Casal di Principe) triggered a 500-Foot Step-Out Sampling Event, which was conducted as part of Phase II because four of the residences (i.e., 1380, 1767, 0333, and 1735), in Study Areas 3, 5, 8 and 8, respectively, did not have any neighboring residences within 500-feet that were occupied by USN Personnel that had not already been sampled as part of Phase I. Figure 4-26 presents the three residences that triggered the Step-Out Sampling Event and their neighboring residences within 500 feet that were occupied by USN Personnel. Only tap water samples were collected from these residences. The tap water samples were analyzed for VOCs, SVOCs, dioxins/furans, pesticides, PCBs, metals, bacteriological parameters, radiological parameters, anions, and field parameters. The sampling results from these residences were compared to RSLs and USMCLs and the risks are summarized in the box presented below.

Summary of Screening Risks for 500-Foot Step-Out Sampling Event Residences

Water Source at the Time Samples Were Collected ³⁰	500-Foot Step-Out Residence	Scenario 1 – Risks Calculated Based on the Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas)			Scenario 2 – Risks Calculated Based on the Ingestion + Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas)

		Total CNCEF	Total CCEF	Risk Management Category	Total CNCEF	Total CCEF	Risk Management Category
Notes:							
¹ Residence 0246 is a Phase II location but is presented above and on Figure 4-26 because it is located within the 500-Foot Step-Out Area.							

The risks for all 10 of the 500-Foot Step-Out Sampling Event residences were considered Unacceptable based on the PHE risk management criteria. Tetrachloroethene in tap water was responsible for the majority of the risks at all 10 locations. Nitrate and uranium were also detected in the tap water at concentrations that exceeded RSLs. Total coliforms were detected in tap water samples from all 10 residences at concentrations exceeding the USMCL.

4.5.1.2 Incremental Risks Summary for the 1500-Foot Step-Out Sampling Event

Twenty-five residences that were sampled during the Phase I investigation had Unacceptable concentrations of tetrachloroethene in tap water that was obtained from private wells at the time samples were collected. Figure 4-27 presents the 25 residences that were occupied by USN Personnel located within 1,500 feet of the initial 500-Foot Step-Out Sampling Event residences. Tap water and soil gas samples were collected from the 1,500-Foot Step-Out Sampling Event residences and were analyzed for VOCs (the tap water samples were also analyzed for field parameters). The sampling results from these residences were compared to RSLs and USMCLs and the risks are summarized in the box presented below.

Private Well	1621	0.0	9.9	Acceptable	0.0	22.3	Unacceptable

Scenario 1 – Risks Calculated Based on the Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas) – The risks for 16 of the 25 (64%) of the residences were Unacceptable. Five of the six residences that were sampled that obtained their tap water from a public source had Acceptable risks. As presented in Table 4-3, soil gas was responsible for Unacceptable risks at 15 of the 25 (60%) residences that were sampled for soil gas. Tap water was responsible for Unacceptable risks at two of the nine residences (22%) that were sampled for tap water. The residences with Unacceptable tap water results obtained their tap water, at the time samples were collected, from private wells. In addition, the Unacceptable tap water results were co-located with Unacceptable soil gas results. Tetrachloroethene in soil gas was responsible for the Unacceptable risks at 11 of the 25 (44%) residences. Benzene, chloroform, and ethylbenzene in soil gas were responsible for the Unacceptable risks at two, four, and one of the residences sampled, respectively.

Scenario 2 – Risks Calculated Based on the Ingestion + Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas) – The risks for 20 of the 25 (80%) of the residences were Unacceptable. The media and COPCs responsible for the majority of the risks were consistent with the risk discussed in the previous paragraph.

4.5.2 Incremental Risk Summary for the Villa Literno Sampling Event

Villa Literno is a *comune* located in Study Area 5. The tap water results from two residences that obtained their tap water from private wells (i.e., 1767 which was sampled during the Pilot Study and 2016 which was sampled as part of Phase II) had Unacceptable concentrations of tetrachloroethene. These results indicated the potential for groundwater and/or soil contamination in this area. The USN was unable to obtain any information regarding the potential source(s) or the extent (i.e., vertical or horizontal distribution) of tetrachloroethene in groundwater from the Italian regulatory agencies. At the time residences 1767 and 2016 were sampled, there were no residences located within 500-feet of these two

residences that were occupied by USN Personnel, so Step-Out sampling was not performed. However, because information indicated that the majority of the residences located in Villa Literno obtained their drinking water from private wells, the USN decided to collect tap water (from private wells) and soil gas samples from homes within Villa Literno in order to evaluate the potential for groundwater contamination.

Figure 4-28 presents the four residences that were occupied by USN Personnel and sampled as part of the Villa Literno Sampling Event. Tap water and soil gas samples were collected from these residences. The tap water samples were analyzed for VOCs, dioxins/furans, metals, bacteriological parameters, radiological parameters, anions, and field parameters. The soil gas samples were analyzed for VOCs. The sampling results for these residences were compared to RSLs and USMCLs and the risks are summarized in the box presented below.

Summary of Screening Risks for Villa Literno Residences

Water Source at the Time Samples Were Collected	Villa Literno Residence	Scenario 1 – Risks Calculated Based on the Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas)			Scenario 2 – Risks Calculated Based on the Ingestion + Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas)		
		Total CNCEF	Total CCEF	Risk Management Category	Total CNCEF	Total CCEF	Risk Management Category
Private Well	1751	0.1	70.5	Unacceptable	2.6	241.9	Unacceptable
Private Well	1756	0.1	89.6	Unacceptable	2.6	222.5	Unacceptable
PUBLIC	1766	0.0	1.5	Acceptable	1.3	4.1	Unacceptable
Private Well	1771	0.1	26.5	Unacceptable	2.8	116.6	Unacceptable

Scenario 1 – Risks Calculated Based on the Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas) – The risks for three of the four (75%) of the residences were Unacceptable. Three of the four residences that were sampled obtained their tap water from private wells. As presented in Table 4-3, soil gas was responsible for Unacceptable risks at three of the four (75%) residences. Only residence 1766 did not have Unacceptable risks associated with soil gas. Tap water was responsible for Unacceptable risks at three of the four (75%) residences. The Unacceptable tap water results were co-located with Unacceptable soil gas results. Tetrachloroethene in soil gas was responsible for the Unacceptable risks at three of the four (75%) residences. Tetrachloroethene in tap water was responsible for the Unacceptable risks three of the four (75%) residences.

Scenario 2 – Risks Calculated Based on the Ingestion + Inhalation of Tap Water Vapors and Inhalation of Indoor Air (via Soil Gas) – The risks for all of the residences were Unacceptable. The media and COPCs responsible for the majority of the risks were consistent with the risk based on the inhalation of tap water vapors and inhalation of indoor air (via soil gas) that were discussed immediately above. In addition, fecal coliform, nitrate, and total coliforms were detected in tap water at concentrations that exceeded the USMCL at (one of four residences), (three of four residences), and (two of four residences), respectively. Uranium was detected in tap water at one of the four residences at a concentration that exceeded the CEF of 10; however, the concentration did not exceed the USMCL.

4.5.3 Incremental Risk Summary for Active Soil Gas Sampling at Phase I Residences that Exceeded Risk Criteria Based on Passive Soil Gas Results

During Phase I of the PHE, passive soil gas samples were collected from residences. Passive soil gas samples provided results in units of total mass (e.g., ug) of the chemical and not in the units of concentration (e.g., ug/m³) that were needed to evaluate potential health risks. Therefore, the Phase I passive soil gas results were converted from mass to concentration by applying "conversion" factors that were provided by the GORE Company. These results enabled a limited but quantitative evaluation of the potential for VI from soil gas to indoor air. The results of the Phase I SRE identified seven residences that potentially had Unacceptable risks associated with VI from soil gas. During Phase II of the PHE, active soil gas samples were collected from residences using USEPA Method TO-15 (i.e., SUMMA Canisters). Active soil gas sampling results provide results in units of concentration (e.g., ug/m³) and are more reliable for evaluation in a quantitative risk assessment. Because of the uncertainty associated with the passive soil gas results, the seven residences that had Unacceptable results, based on passive soil gas results, were re-sampled using active soil gas techniques to confirm the initial results. The box below compares the risks predicted based on the passive and active soil gas sampling.

Summary of Screening Risks for Active Soil Gas Sampling of Phase I Residences That Had Unacceptable Risks Associated with Passive Soil Gas Samples

Water Source at the Time Samples Were Collected	Residence	Phase I Passive Soil Gas Risks Calculated Based on Inhalation of Vapors from Soil Gas Only			Phase II Re-Sampling Active Soil Gas Risks Calculated Based on Inhalation of Vapors from Soil Gas Only		
		CNCEF	CCEF	Risk Management Category	CNCEF	CCEF	Risk Management Category
PUBLIC	0199	0.0	6.3	Acceptable ¹	0.1	44.6	Unacceptable
Private Well	0238	0.0	28.3	Unacceptable	0.6	421.8	Unacceptable
Private Well	0548	0.0	0.2	Unacceptable ²	30.5	29,168.8	Unacceptable
PUBLIC	0831	1.3	877.7	Unacceptable	1.1 ⁽³⁾	793.2 ⁽³⁾	Unacceptable
PUBLIC	0949	0.8	555.0	Unacceptable	0.0	28.4	Unacceptable
PUBLIC	1151	0.5	460.7	Unacceptable	0.0 ⁽³⁾	27.2 ⁽³⁾	Unacceptable
PUBLIC	1157	0.0	8.9	Unacceptable ²	0.0 ⁽³⁾	10.5 ⁽³⁾	Unacceptable

Notes:
¹The passive soil gas risks at this residence were Acceptable; however, the location was re-sampled during Phase II for comparison purpose only.
²The passive soil gas risks were Acceptable at these residences. However, when the passive soil gas risks were combined with the risks from other media (e.g., risks from tap water and/or soil), the total risk for the residence was considered Unacceptable.
⁽³⁾The active soil gas risks presented for this location were calculated prior to applying a multi-story VAF. Risks calculated with the multi-story VAF are presented in Table 4-3.

The results presented in the box above generally indicate that there was a poor correlation (R = -0.33) between the passive soil gas CCEFs and active soil gas CCEFs. In some cases the passive soil gas CCEFs were significantly less than the active soil gas CCEFs and in other cases the passive soil gas CCEFs were significantly greater than the active soil gas CCEFs. The only residences with comparable CCEFs were residences 0831 and 1157. The COCs responsible for the majority of the risks identified in passive and active soil gas were similar. In passive soil gas, chloroform, tetrachloroethene, and trichloroethene were responsible for the majority of the risks at (three of seven residences), (four of seven residences), and (two of seven residences), respectively. In active soil gas, carbon tetrachloride,

chloroform, and tetrachloroethene were responsible for Unacceptable risks at (one of seven residences), (one of seven residences), and (seven of seven residences), respectively.

4.5.4 Incremental Risk Summary for Active Soil Gas Sampling at Parco Eva and Parco Le Ginestre

Parco Eva and Parco Le Ginestre were sampled for tap water, soil, and soil gas as part of Phase I of the PHE (see Figure 2-1). The passive soil gas concentrations of tetrachloroethene from Parco Eva exceeded the RSL and had a maximum CEF of 9.9. Tetrachloroethene was also detected in tap water, which was obtained from a public source at concentrations exceeding the RSL. The passive soil gas concentrations of tetrachloroethene from Parco Le Ginestre exceeded the RSL and had a maximum CEF of 171.7. Tetrachloroethene was also detected in tap water, which was obtained from a public source at concentrations exceeding the RSL. In addition, tetrachloroethene was detected in irrigation water samples from Parco Le Ginestre. In summary, the Phase I results from Parco Eva and Parco Le Ginestre indicated that there may be a potential VI concern at these locations. Therefore, during Phase II of the PHE, three active soil gas samples were collected from Parco Eva and two active soil gas samples were collected from Parco Le Ginestre. The box below summarizes the risk evaluation of the active soil gas samples that were collected during Phase II.

**Summary of Screening Risks for Phase II Active Soil Gas Sampling Results
from Parco Eva and Parco Le Ginestre**

Parco	Sample	CNCEF	CCEF	Risk Management Category	Chemicals Responsible for the Majority of the CNCEF	COCs Responsible for the Majority of the CCEF
Parco Eva	EV50SG001	14.1	2.1	Unacceptable	Acrolein ¹	Tetrachloroethene
Parco Eva	EV51SG001	15.3	85.1	Unacceptable	Acrolein ¹	Tetrachloroethene
Parco Eva	EV52SG001	6.7	69.4	Unacceptable	Acrolein ¹	Chloroform Bromodichloromethane Ethylbenzene Tetrachloroethene
Parco Le Ginestre	LE50SG001	65.3	13.3	Unacceptable	Acrolein ¹	Benzene Chloroform Tetrachloroethene
Parco Le Ginestre	LE51SG001	0.9	49.7	Unacceptable	No Chemicals were detected at concentrations with an NCEF > 1.	1,2-Dibromoethane Chloroform Tetrachloroethene
Notes:						
¹ As per the <i>Technical memorandum: Identification of Chemicals in Soil Gas that may be Associated with Vapor Intrusion</i> (see Appendix D), acrolein was determined to be a non-VI COPC. As such, it <u>was not</u> evaluated for soil gas risks using soil gas data but was evaluated for ambient air risks using ambient air data.						

As presented in the box above, the risk for each of the active soil gas samples that were collected during Phase II from Parco Eva and Parco Le Ginestre were Unacceptable based on the PHE risk management criteria. Tables 4-22 and 4-23 present the chemical-specific risks for each sample that was collected at the Parco Eva and Parco Le Ginestre, respectively. Acrolein was responsible for the majority of the CNCEF; however, the concentrations of acrolein in the soil gas samples were similar to concentrations of

acrolein in ambient air³¹. Therefore, the acrolein results may be more indicative of risks associated with exposures to ambient air rather than VI from a subsurface source. Chloroform and tetrachloroethene were responsible for the majority of the CCEF and were potentially a VI concern. Benzene, bromodichloromethane, ethylbenzene, and 1,2-dibromoethane were detected at concentrations exceeding their RSLs but were not responsible for Unacceptable risks in any sample.

³¹As per the *Technical Memorandum Identification of Chemicals in Soil Gas That May be Associated with Vapor Intrusion* (see Appendix D), acrolein was determined to be a non-VI COPC. As such, it was not evaluated for soil gas risks using soil gas data but was evaluated for ambient air risks using ambient air data.

SECTION 5 – UNCERTAINTY ANALYSIS

The purpose of this Uncertainty Analysis is to identify key components of the SRE that could significantly impact the results of the evaluation. The key uncertainties evaluated in this analysis were associated with:

- Lack of historical data and institutional knowledge about hazardous waste sites in Campania
- Representativeness of the analytical data used in the SRE
- Identification of constituents in soil gas that may be associated with VI
- Vapor attenuation factors used to predict indoor air concentrations from soil gas
- Step-out sampling data gaps
- Conceptual site model and exposure assumptions
- Toxicity values

Uncertainty occurs because of a lack of information. In other words, uncertainty is an expression of the confidence we have that a parameter (e.g., EPC, VAF) accurately reflects the population being evaluated.

Variability, on the other hand, is an expression of the range of differences between individuals observed for a given population. It is not possible to eliminate variability in heterogeneous populations.

5.1 Lack of Historical Data and Institutional Knowledge about Hazardous Waste Sites and Improper Waste Disposal in Campania

The magnitude of the problem associated with trash collection, uncontrolled open burning of uncollected trash, and widespread dumping of chemical and other potentially hazardous waste was compounded by the lack of basic information about “contaminated sites” in Southern Italy. As discussed in Volume III, there were thousands of contaminated waste sites in the Campania Region and the history of illicit waste disposal dates back to the early 1980s (ARPAC, 2009). Figure 1-3 shows the approximate location of potential waste sites within the study areas. In most cases, the type of waste that was dumped or burned at these locations is unknown. A more detailed depiction of the known waste sites by category (i.e., abandoned waste sites, sites where contamination has been verified, and potentially-contaminated sites for which there is no analytical data available yet to confirm contamination above the concentration threshold) is presented in the *Naples Public Health Evaluation, Volume III: Phase I & Phase II* (NMCPHC, 2010). However, CNREURAFSWA's requests to ARPAC for basic information on location (e.g., Global Positioning System coordinates) and site characterization (e.g., what constituents, what concentrations, etc.) were typically unproductive.

Figure 1-3 also presents the six “Sites of National Interest” (similar to the USEPA Superfund Sites on the National Priorities List) identified in Campania. Of particular concern were the Bagnoli-Coroglio Site of National Interest (for Study Areas 1 and 2) and the Napoli Orientale Site (for Study Area 3), and the other seven study areas were located within the footprint of the Litorale Domito Flegreo e Agro Aversano Site. These were the only waste sites known by the USN; the majority of the sites were not characterized in terms of extent of contamination, nor remediated (cleaned up). There may be other sites containing urban or hazardous waste that have not yet been documented by Italian agencies.

Trash collection and disposal problems have plagued Naples and the Campania Region for decades. The city of Naples generates an estimated 8,000 metric tons of trash daily, much of which was set on fire during the trash crisis in 2007 and 2008, which released pollutants and smoke and potentially posed a health risk to residents (Italian Ministry of the Interior, National Fire Department, Department of Fire, Rescue, and Civil Defense, 2008). Releases of contaminants to ambient air (through uncontrolled burning of trash) in addition to releases to subsurface soil and groundwater were confounding factors that made it difficult to interpret multi-media data and determine the extent of contamination. The multi-media impact, lack of historical data, and lack of institutional knowledge were significant uncertainties that impacted sampling design, data interpretation, and the calculation of risk.

5.2 Representativeness of the Analytical Data Used in the SRE

A key input into this SRE was the measured constituent concentrations in tap water, soil, soil gas, and ambient air. The goal of environmental sampling programs that contribute data to human health risk assessments is to characterize the concentrations and locations of constituents in media of interest in order to quantify representative potential human exposures and subsequent potential human health risks. Every effort was made to optimize the PHE Sampling Events; however, there were inherent uncertainties associated with representativeness of the constituent data set, as discussed below.

5.2.1 Sampling Design

During Phase I, a biased sampling design was implemented to sample areas within the Campania Region, where USN Personnel worked and lived that, based on available information, had the highest potential of being impacted by the effects of hazardous waste that had been disposed of improperly. Italian maps showing the locations of documented trash and chemical dump sites³² were reviewed (see Figure 2-1) to identify candidate residences, from these presumed "worst-case" areas, that were occupied by U.S. Personnel for sampling.

To achieve this, Italian data regarding trash and chemical dump sites were reviewed in order to collect samples from these "worst-case" areas (see Figure 1-3). This is a key uncertainty because it was assumed that the Italian data used to identify the "worst-case" areas for sampling were accurate. Since no constituent-specific information was available from the Italian Government with respect to the specific dump sites (presented on Figure 1-3), it was not feasible to prioritize sampling in areas with constituents that were the most toxic or were present in the highest concentration. Consequently, all dump sites were assumed to have the same potential risk to human health. This approach posed problems because of the heterogeneous nature of the constituent composition of trash and because a variety of different constituents were likely dumped at different times and locations throughout the Campania Region.

Phase II sampling was designed to improve the spatial/geographic distribution of sampling locations, delineate clusters of residences that exceeded risk criteria, and incorporate lessons learned from Phase I. During Phase II of the SRE, a more comprehensive, systematic sampling design was implemented. However, as shown on Table 2-1 and Figure 2-1, sampling was unevenly distributed throughout the nine

³²These maps did not differentiate trash sites from chemical dump sites. Therefore, it was not possible to determine if the residences that were selected for sampling as part of the PHE were near trash sites or chemical dump sites.

study areas (ranging from 11 residences in Study Area 9 to 146 residences in Study Area 8) because samples could only be collected from areas where USN Personnel work and live and where the tenant and landlord agreed to allow sampling.

5.2.2 *Representativeness of a Single Sampling Event for Evaluating Long-Term Exposure*

In most cases, the risks presented in this SRE were based on a single-sampling event at a specific residence. Cost, schedule, and the practical limitations of working in a foreign country made it unfeasible to collect multiple samples from each residence. Sampling was almost always limited to one sample per medium and it was rarely an option to return and collect additional samples. As summarized below, a single sample only provides a "snapshot" of concentrations that were present in tap water, soil, and soil gas. Results from these samples may or may not be representative of the long-term concentrations at a residence:

- **Tap Water** – Concentrations in tap water from presumed shallow, private wells may vary over time due to factors such as the time of year, the amount of associated rainfall, and the amount of aquifer pumping performed by the resident and/or their neighbors.
- **Soil** – The primary concern associated with the representativeness of soil concentrations was the spatial density of the samples (soil concentrations typically are not impacted by temporal variability). The uncertainty associated with the spatial density of soil samples was addressed by collecting composite soil samples at residences in order to obtain greater spatial coverage of the areas being sampled. However, this only applied to non-VOC analyses. Only a single sample was collected for VOC analysis because VOC samples cannot be composited without the loss of COPCs during the compositing process.
- **Soil Gas** – Collecting near-slab or sub-slab soil gas samples is one of the most common methods for assessing VI. However, there is more spatial and temporal variability in soil gas than in indoor air. For example, detailed field investigations of the VI process at Altus Air Force Base (AFB) and Hill AFB (McHugh and Nickels, 2008) demonstrated that at least six soil gas samples were required to achieve the same level of accuracy in estimating the mean soil gas concentration (i.e., within 67% of the population mean over 90% of the time) in comparison to a single indoor air sample and two ambient air samples. Temporal variability (on the time scale of months) was found to be similar to spatial variability. A USEPA evaluation of VI at 15 homes near the Raymark Superfund Site in Connecticut (a site with known groundwater contamination) showed that variability between sub-slab samples ranged from 20% to over 100% depending on the building and chemical, indicating that at least three samples were optimal for a more in-depth soil gas evaluation (DiGiulio and Paul, 2006). VI guidance in the U.S. generally does not specify a minimum number of soil gas samples, although the New Jersey Department of Environmental Protection (NJDEP) recommends at least two near-slab soil gas samples on either side of a building (NJDEP, 2005), because soil gas is evaluated in conjunction with other multi-media data to evaluate VI.

The spatial and temporal uncertainties associated with the tap water and soil gas data were not applicable to the ambient air data because ambient air samples were collected from nine monitoring stations that were located in each of the study areas as part of the year-long ambient air sampling and monitoring

program. The year-long program reduced uncertainties associated with meteorological conditions over various seasons and weather conditions, as well as the temporal and spatial effects of anthropogenic sources of constituents (i.e., resulting from the influence of humans) in ambient air (e.g., burning trash). Since the frequency and content of the trash being burned were random during this investigation, it was important to be able to collect multiple samples on multiple days in order to maximize the probability that burn events would occur during the collection of some of the samples³³. Using this approach, a total of 460 ambient air samples were collected at nine U.S Government-related facilities between September 2008 and October 2009. Because of the size of the data set, the 95% UCL on the mean ambient air concentration was used to determine the EPC for each study area³⁴.

Typical tour lengths at Naples are between three and six years. The SRE assumed that USN Personnel could be exposed to constituents for 30 years. Using environmental sampling results for tap water, soil, and soil gas from a single sampling event incorporated a substantial degree of conservatism and likely over-estimated risk because the concentrations may not be representative of long-term conditions.

5.2.3 *Spatial Sample Density*

Combined, the nine study areas evaluated in the PHE comprise approximately 395 square miles, which is considered a large area to evaluate. Due to jurisdictional and legal Host Nation requirements, samples could only be collected from areas where USN Personnel work and live, and then only with the permission of the tenant and landlord. Additionally, there were a number of media that were potentially impacted (i.e., tap water, soil, soil gas, and ambient air). The large study, area combined with the number of media evaluated, introduced uncertainty with regard to the spatial density of samples for the SRE (see Figure 4-3). There may be areas where samples were not collected that have affected media. The limited access to residences where USN Personnel lease property resulted in variable sample density across the study areas.

5.2.4 *Background Concentrations of Inorganic Chemicals in Tap Water and Soil*

Determining representative background concentrations for inorganic constituents is an important step in the process of characterizing risks. In the Campania Region, background concentrations of arsenic in soil and tap water exceeded RSLs. In fact, in almost all cases, the concentrations posed Unacceptable risks based on the PHE risk management criteria. Since the concentrations of arsenic are naturally occurring and are likely associated with volcanic activity in the region, arsenic was not included in the incremental risk calculations presented in this report. However, arsenic was included in the total (background plus incremental) risks for comparison purposes (see Section 4.2).

Overall, the uncertainty associated with the determination of background concentrations was minimized by incorporating site-specific background data from the Naples area (Cicchella, Domencio et al., 2005).

³³Ambient air samples were collected every nine days for approximately the first seven months, and then every six days for the remainder of the program. Both sampling cycles ensured that ambient air sample collection did not correlate with regularly-scheduled weekly regional events, so that an unintended correlation between sample collection and potential weekly air emissions was averted (Tetra Tech, 2010a; Tetra Tech, 2010b).

³⁴Refer to Section 4.1 for explanation on the development of EPCs.

5.2.5 *Ambient Air*

5.2.5.1 *Availability of Background Ambient Air Data from Cities in Italy*

Determining representative background concentrations for constituents in ambient air is necessary to accurately characterize risks. Background ambient air concentrations for the Campania Region were not available for the nearly 241 constituents that were analyzed as part of the PHE – Italian background ambient air data were limited to priority pollutants such as particulate matter less than 10 microns in diameter (PM₁₀), ozone, et cetera. Therefore, ambient air concentrations from representative cities in the U.S. were evaluated and compared to Naples ambient air sampling results to put the Naples air concentrations into context with regard to what USN Personnel might be exposed to in typical urban air if they were stationed in the U.S.³⁵ The 95% UCL on the mean ambient air concentrations from six U.S. cities (i.e., San Diego, California; Los Angeles, California; Seattle; Washington; Houston, Texas; Midlothian, Texas; and Washington, DC) found in the USEPA’s 2007 Air Toxics Database (USEPA, 2007) were used to represent typical urban ambient air concentrations in the U.S. These cities were selected because they have one or more attributes that are similar to Naples and the Campania Region, such as (1) availability of ambient air data, (2) dense residential, urban, and industrial development, (3) coastal location, and (4) USN presence. Thus, the assumption that urban air in the Campania Region is similar to urban air in the U.S. remains an uncertainty in this analysis. This uncertainty adds to the complexity of determining whether or not the ambient air results in Naples are similar to ambient air risks in the six U.S. cities. As a result, this limits the ability to reach a firm conclusion on the ambient air risks in Naples as either less than or greater than the ambient air risks in the six selected U.S. cities.

5.2.5.2 *Comparison of Naples and U.S. Ambient Air Data*

In order to compare Naples ambient air data and risks to U.S. ambient air data and risks, a data set with identical contaminant lists and timeframes was needed. A U.S. urban ambient air data set with an exact “one-to-one” correspondence to the ambient air data collected in Naples was not available, which led to some degree of uncertainty regarding the evaluation of risks (i.e., risk could have been underestimated due to a lack of data or overestimated due to additional data).

Moreover, no one city’s data set could be considered a perfect comparison to Naples. For example, New York may be considered most representative of Naples because of its large, densely-populated, industrial and urban setting. However, the rural portion of Naples (located outside of the downtown area) could result in the presence of other contaminants that are typically uncharacteristic of New York. In addition, “behavioral” differences between U.S. cities and Naples could result in the presence of different constituent. For example, acrolein is a principal air constituent in Naples, likely because of the abundant presence of diesel exhaust emissions, whereas diesel engine use in the U.S. is less prevalent.

5.2.5.3 *Approach Used to Identify Ambient Air Concentrations in U.S. Cities for Comparison to Naples*

Finding constituent values in the USEPA’s 2007 Air Toxics Database that corresponded with the constituents detected in Naples was paramount to this investigation. When obtaining comparison values,

³⁵ Refer to Section 4.1 for explanation on the development of EPCs.

priority was given to finding values in the 2007 USEPA Air Toxics Database for constituents that were detected in ambient air samples from the Naples PHE that exceeded their RSLs. Twenty one of the 27 constituents in Naples ambient air that exceeded their RSLs (21 of 27 or 78%) had corresponding values in the USEPA's 2007 Air Toxics Database. Comparison values were not available in the USEPA's 2007 Air Toxics Database for the following six constituents that exceeded their RSLs in Naples ambient air (see Table 4-19):

1. 1,1,1,2-Tetrachloroethane – The CEFs from the nine study areas ranged from 0.3 to 1.1.
2. 1,2-Dibromo-3-chloropropane – The CEFs from the nine study areas ranged from 397 to 727.
3. Bromodichloromethane – The CEFs from the nine study areas ranged from not detected to 2.3.
4. Cobalt – The CEFs from the nine study areas ranged from 0.52 to 1.7.
5. Dibromochloromethane – The CEFs from the nine study areas ranged from not detected to 2.3.
6. Total Dioxin/Furans (2,3,7,8-TCDD TEQs) – The CEFs from the nine study areas ranged from 0.60 to 40.

The lack of corresponding values for these six constituents, especially for 1,2-dibromo-3-chloropropane, had a significant impact on the uncertainty of the risk assessment of ambient air. As presented in Table 4-21, when all constituents that were detected in ambient air in Naples, regardless if they had corresponding values in the USEPA's 2007 Air Toxics Database or not, were included in the risk calculations, the CCEF for the nine study areas were, on average, approximately five times higher than the CCEF calculated based on the USEPA's 2007 Air Toxics Database. However, when only constituents that were detected in ambient air in Naples that had corresponding values in the USEPA's 2007 Air Toxics Database were included in the risk calculations, the CCEF for the nine study areas were, on average, approximately 0.8 times lower than the CCEF calculated based on the USEPA's 2007 Air Toxics Database (see Table 4-21). This is a significant finding and demonstrates the sensitivity of the CCEF results to the inclusion of the 1,2-dibromo-3-chloropropane concentration detected in ambient air in Naples. It is important to note that this finding does not indicate that risks associated with ambient air in Naples are similar to the risks associated with ambient air in the U.S. It is not possible to make this determination without corresponding values from the U.S. Key information regarding 1,2-dibromo-3-chloropropane that should be considered when making risk management decisions regarding ambient air samples collected during the Naples PHE is discussed in the following subsection.

5.2.5.4 1,2-Dibromo-3-Chloropropane

Of the six constituents that were detected in ambient air in Naples at concentrations that exceeded their RSLs and for which comparison values were not available in the USEPA's 2007 Air Toxics Database, 1,2-dibromo-3-chloropropane was responsible for the majority of the cancer risks in nine study areas. 1,2-Dibromo-3-chloropropane is a nematicide and was used in agriculture as a soil fumigant (i.e., it was not applied using aerial sprayers). It was typically applied via covered shallow trenches where liquid was deployed and then the 1,2-dibromo-3-chloropropane quickly evaporated in the soil column where the subsoil was then fumigated (Albrecht et al. 1985). Based on the typical application method, it would be unusual to detect 1,2-dibromo-3-chloropropane in ambient air at locations distant from the point of

application (Albrecht et al. 1985). 1,2-Dibromo-3-chloropropane was banned in the U.S. in 1979; however, Hawaii was allowed to use 1,2-dibromo-3-chloropropane until 1985. 1,2-Dibromo-3-chloropropane is persistent in soil and groundwater and takes several months to breakdown in air (ATSDR, 1995). As presented in Table 4-20, 1,2-dibromo-3-chloropropane was responsible for, on average, 80% of the ambient air CCEFs for the nine study areas, but a corresponding value was not available (i.e., samples were not analyzed for it) in the USEPA's 2007 Air Toxics Database. The lack of an available corresponding 1,2-dibromo-3-chloropropane value in the USEPA's 2007 Air Toxics Database is a significant data gap in the PHE because a direct comparison between cancer risks in Naples and U.S. can't be performed. In addition, there is uncertainty with the representativeness of the ambient air results for 1,2-dibromo-3-chloropropane evaluated in the PHE, which include:

1. No information that definitively stated that 1,2-dibromo-3-chloropropane was banned in Italy could be found.
2. 1,2-Dibromo-3-chloropropane was infrequently detected in ambient air samples collected during the Naples PHE (i.e., 30 of 441 [6.8%]). Appendix C presents summary statistics, including the frequency of detection, for each constituent and study area).
3. 1,2-Dibromo-3-chloropropane was detected in all nine study areas at similar concentrations just above the detection limit of 0.0001 mg/m³.
4. The detection limit (i.e., 0.0001 mg/m³) is 625 times greater than the RSL which is (1.6E-07 mg/m³). This is important because half the detection limit was included in the calculation of the EPC.
5. All of the 1,2-dibromo-3-chloropropane detections occurred between June 2009 and August 2009. It is unclear why 1,2-dibromo-3-chloropropane was only detected during this time frame and was not detected during the previous summer, fall, winter, or spring. These detections were observed in all nine study areas over the same time period, but did not correlate with agricultural areas. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Study Area 2 where the sampling station was located at the U.S. Consulate. The U.S. Consulate is located in downtown Naples, Italy and is miles from any agricultural area.

Despite these uncertainties, there was no technical reason to exclude the ambient air results for 1,2-dibromo-3-chloropropane from the Naples PHE. However, these uncertainties should be considered when making risk management decisions.

5.2.6 Passive Soil Gas Sampling Results

The passive soil gas concentrations evaluated in Phase I were based on results obtained from Gore-Sorber Modules, which are patented, passive-diffusion sorbent-based samplers that collect samples for VOCs, SVOCs, and pesticides. As discussed in Section 2.1.2.3, the passive soil gas collection process measures chemical mass rather than concentration and is therefore qualitative in nature. Soil gas concentrations were estimated by Gore using the mass of the constituent detected in combination with information obtained regarding the soil type in the Campania Region. Although soil gas concentrations were estimated using default assumptions regarding soil characteristics, the information is not truly suitable for

a quantitative risk assessment. The data collected via this process was useful for screening purposes only to determine if there was a potential for VI.

To address the uncertainty associated with passive soil gas results, active soil gas samples were collected from 201 residences in all nine study areas between November 2008 and July 2009 (Tetra Tech, 2010a). In addition, Phase I residences that had Unacceptable results associated with passive soil gas (i.e., residences 0238, 0949, 1151, and 0831) were re-sampled using active soil gas sampling techniques during Phase II. Active soil-gas sampling techniques provide results in units of concentration that can be evaluated directly in the risk assessment. Active soil-gas sampling is viewed by most experts in the VI field as the most reliable method for collecting soil gas for use in risk assessment and reduced the uncertainty.

5.2.7 Usability of Analytical Data for Naphthalene and Acetaldehyde in Active Soil Gas Samples

As discussed in Section 2.1.2.3, naphthalene and acetaldehyde were among the constituents tested for in active soil gas and ambient air during Phase II using USEPA Methods TO-13A and TO-15 (for naphthalene) and TO-11 and TO-15 (for acetaldehyde). Inconsistencies between the results obtained from two methods (TO-13A and TO-15 for naphthalene and TO-11 and TO-15 for acetaldehyde) led to further research and Tetra Tech determined that the active soil gas (and select ambient air) data for naphthalene and acetaldehyde analyzed by the USEPA Method TO-15 were not suitable for inclusion in the SRE. The lack of soil gas data for naphthalene and acetaldehyde resulted in uncertainty as to whether or not these COPCs were potentially a concern to human health via the VI pathway. The significance of this data gap on the risk assessment cannot be quantified.

5.2.8 Lack of Speciated Results for all Residences with Radionuclides in Tap Water and Irrigation Water

There were uncertainties associated with speciation of tap water samples for radioactive constituents (i.e., radionuclides). Most drinking water sources have very low levels of radionuclides, and naturally-occurring radionuclides are generally not evaluated as part of a human health risk assessment. During Phase I of the PHE, tap water samples (i.e., from private wells, irrigation wells, and public sources) were analyzed for: (1) gross-alpha activity and (2) gross-beta activity. The results of the gross-alpha and gross-beta analyses, shown in the box presented below, were used to determine whether or not additional analyses were required for the risk assessment. As described in Appendix G, further radionuclide speciation screening was performed.

Summary of Radionuclide Sampling Results

Radionuclide	Number of Tap Water & Irrigation Water Samples Analyzed (includes Field Duplicates and Results from U.S. Government-Related Facilities)	Number of Detected Results	Project Screening Criterion	Number of Residences with Samples Exceeding Screening Criterion
Gross-Alpha	646 ^(a)	214	15 pCi/L	3 ^(b)
Gross-Beta	646 ^(a)	358	8 pCi/L	58 ^(c)
Speciated Results	37 ^(d)	0	Radium-226/228 – 5 pCi/L Strontium-90 – 8 pCi/L Other beta/photon emitters – 50 pCi/L	3 (Radium-228) 0 0
Notes:				
^a Total number of samples analyzed includes tap water, irrigation water, samples from U.S. Government-related facilities, and field duplicates.				
^b Gross-Alpha samples from three locations exceeded the screening criterion but only two were from private residences located on the Italian Economy. The other sample with a screening exceedance was an irrigation water sample from Parco Le Ginestre.				
^c Gross-Beta samples exceeded the screening criterion at 58 residences located on the Italian Economy. At two of these locations, samples also exceeded the gross-alpha activity screening criterion.				
^d According to the provisions of QAPP and Radiological Screening Procedure, 58 locations should have been reanalyzed for speciation but speciation was possible for only 37 residences because of logistical difficulties associated with gaining access to 22 residences to collect additional tap water samples (see Table G-2). This count (i.e., 22) includes one residence, #1614, where the original gross-beta sample result exceeded 50 pCi/L but water source was blended; re-sampled as pre-lease location on 10/17/08 but plumbing was changed to public water source and gross-beta was < 8 pCi/L after K-40 correction; outside well was re-sampled on 5/23/09 (sample named 1614IW - speciation results were not detected).				

Six hundred and forty-six (646) tap water samples from residences located on the Italian economy and U.S. Government-related facilities were analyzed for gross-alpha and gross-beta activity. Gross-alpha activity was detected in 214 water samples; however, only tap water samples from three residences exceeded the screening criterion. Gross-beta activity was detected in 358 water samples; however, only 58 locations exceeded the screening criterion (37 of these residences were located on the Italian economy). The three gross-alpha exceedances were collocated with three of the gross-beta exceedances. As discussed in Appendix G, 22 of the 37 residences with screening level exceedances of gross-alpha and gross-beta activity were not re-sampled and speciated because of logistical issues associated with regaining access to the residence for a second time to collect tap water samples. Where collected, all tap water speciated results were below the detection limit for radionuclides, which indicated that the incremental risks at the 16 residences were acceptable and that background sources were responsible for the gross-activity screening-level exceedances.

Further analysis of the data (presented in Appendix G) indicated that speciation results for the 22 residences that could not be re-sampled likely would have been consistent with the 16 speciated results that were nondetected. Furthermore, the lack of speciation did not have a significant impact on the SRE because 20 of the 22 residences had unacceptable ingestion+inhalation and inhalation-only risks due to concentrations of other COPCs. Residence 1877 (a Pre-Lease residence) was acceptable for ingestion+inhalation of tap water and was also acceptable for the inhalation-only of tap water. This residence was characterized as Inconclusive for the ingestion+inhalation of tap water pathway because of the speciation data gap. The residence would still be acceptable for the inhalation of tap water pathway because the speciated COPCs were primarily of concern to human health if ingested and not inhaled (i.e., via inhalation).

5.3 Identification of Constituents in Soil Gas That May be Associated with VI

One of the most challenging aspects of evaluating active soil gas results were determining which constituents were potentially associated with a subsurface source (i.e., groundwater or soil) versus

constituents that were associated with an ambient air and/or indoor air source(s) that may be present in the aerobic-soil and/or leaked into the sample train. These issues were evaluated in detail in Appendix D.

As noted in Appendix D, the VI pathway contributed significantly to the estimated risk at residences on the Italian economy. However, because of the limitations of the soil gas data, decision criteria were established to maximize protectiveness and 1) to err toward presuming a COPC was associated with a subsurface VI source rather than not and 2) to err toward assuming minimum attenuation (i.e., maximum VI migration to indoor air).

A lines-of-evidence approach incorporating a multi-faceted, multi-media evaluation of the data from the nine study areas was used to evaluate soil gas sampling results³⁶. The evaluation focused on 22 (out of 68) COPCs that were detected in any active soil gas sample. Seventeen of the 22 COPCs were determined to be VI COPCs (i.e., associated with subsurface VI sources [soil or groundwater] that could contribute to VI in overlying buildings). Five COPCs were determined to be non-VI COPCs (COPCs in soil gas that may be associated with above-ground sources). Fourteen of the 17 VI COPCs were determined to have the potential to be associated with a subsurface VI source within a specific geographical area (i.e., Localized VI COPCs), and three were determined to be associated with VI at all residences (i.e., Global VI COPCs). The lines-of-evidence approach for identifying COPCs that may be associated with a subsurface VI source versus above-ground ambient air sources is addressed in Appendix D.

5.3.1 *Distinguishing Between VI COPCs and Non-VI COPCs*

The USEPA VI Guidance recommends a tiered approach to VI assessment, consisting of: 1) a preliminary pathway evaluation based on the presence of a volatile source (e.g., groundwater), 2) an evaluation of VOC concentrations using generic or semi-site-specific screening criteria and 3) a site investigation to evaluate VI by direct measurement (USEPA, 2002). Even with a tiered approach and multi-media data, VI investigations are often confounded by background concentrations in indoor and ambient air. In the Campania Region, the USN was severely restricted with regard to where samples could be collected and which media could be sampled at those residences. Hydrogeological and site characterization data were not available and in most cases, it was not an option to re-sample a residence. In lieu of the standard tiered multi-media approach, a less conventional approach was used to differentiate between COPCs from subsurface sources (potentially resulting from poor waste disposal practices) (VI COPCs) and COPCs from other sources (non-VI COPCs from above-ground ambient or indoor air sources). This approach is described in Appendix D.

There was uncertainty in distinguishing between VI COPCs and non-VI COPCs. However, a protective lines-of-evidence approach was used to identify VI COPCs (i.e., three out of four lines of evidence had to support a non-VI COPC classification otherwise a chemical was classified as a VI COPC), so the tendency was to err on the side of concluding a COPC was a VI COPC rather than concluding it was a

³⁶The lines-of-evidence approach (detailed in Appendix D) is a recommended approach for evaluating background and VI in the U.S. Multiple lines of evidence were evaluated systematically to make a determination (i.e., answer a question based on available data). The approach required professional judgment for selecting and evaluating available information.

non-VI COPC. The following four primary lines of evidence were evaluated to determine whether or not a COPC was a VI COPC:

1. COPC Detected in Groundwater and Spatial Distribution of Groundwater is Consistent with Spatial Distribution in Soil Gas
2. Soil Gas and Ambient Air Concentration Frequency Distribution Patterns (e.g., higher frequency distribution for soil gas indicative of VI COPC)
3. Site-Wide Average Soil Gas to Average Ambient Air Ratio Greater than One
4. Mean or Median Soil Gas to Ambient Air Ratio for Residences with Co-located, Co-collected Soil Gas and Ambient Air Data Greater than One

5.3.1.1 *Distinguishing Between Global VI COPCs and Localized VI COPCs*

There was uncertainty associated with determining whether a VI COPC was a Global VI COPC or a Localized VI COPC. Global VI COPCs were evaluated for the VI pathway at all residences where the COPC was detected. Localized VI COPCs were evaluated for the VI pathway at residences where the soil gas concentration exceeded the 95th percentile site-wide ambient air concentration for that COPC. If the soil gas concentration was less than or equal to the 95th percentile site-wide ambient air concentration, then the Localized VI COPC was not evaluated for soil gas risks using soil gas data but was evaluated for ambient air risks using ambient air data. If the Localized VI COPC was detected in soil gas at a concentration greater than the 95th percentile of the site-wide ambient air concentration, then the Localized VI COPC was evaluated for soil gas risks using soil gas data and for ambient air risks using ambient air data. Uncertainties associated with this approach are discussed in Appendix D.

5.4 Vapor Attenuation Factors Used to Predict Indoor Air Concentrations from Soil Gas

Inhalation risks associated with VI of constituents in soil gas to indoor air can vary by orders of magnitude depending on the degree of the attenuation that occurs between soil gas and indoor air. Subsurface conditions and building characteristics vary across the nine study areas, and because building access was not always possible, some soil gas samples were collected sub-slab and some were collected outside of the building (near-slab). Studies conducted by the USEPA and various state agencies have raised concerns as to the appropriateness of near-slab soil gas data in the investigation of the VI pathway (NJDEP, 2005). The NJDEP does not accept exterior soil gas samples as a stand-alone factor in assessing VI due to concerns with false negatives as a function of soil type, soil moisture, or impermeable layers that do not represent conditions beneath the slab. Low permeability layers may also be found under buildings (either naturally or as part of construction) and these layers may explain random or irregular results around a building. The NJDEP does not allow soil gas samples to be averaged across the subsurface around a building; they require each point to be evaluated independently (NJDEP, 2005).

The intent during Phase II was to collect sub-slab soil gas samples at all candidate residences; however, it was not possible to collect sub-slab soil gas samples at all residences (e.g., tenants lived in upper floors with no access to ground floor areas, or in some cases landlords refused to permit sub-slab soil gas sampling). In these instances, near-slab soil gas samples were collected. Approximately 51% of the

active soil gas samples that were collected were sub-slab samples. A comparison of near-slab and sub-slab data for several COPCs (benzene, ethylbenzene, chloroform, tetrachloroethene, 1,2-dichloropropane, carbon tetrachloride, and trichloroethene) from the nine study areas revealed that there was a higher frequency of elevated soil gas to ambient air ratios for sub-slab versus near-slab samples. Sixty-one (61) percent of the near-slab soil gas samples had soil gas to ambient air ratios at or below one in comparison to 38% of the sub-slab soil gas samples. Without site-specific lithology or hydrogeologic data, it is not possible to determine whether or not the near-slab samples were representative of conditions beneath the buildings. The uncertainties associated with soil gas results were addressed in a manner that assumed a higher, rather than a lower, possibility of VI. However, all soil gas sample concentrations, regardless of how they were collected, were compared to RSLs that were calculated using the USEPA's default VAF (α) of 0.1 (normally used for sub-slab soil gas), which was also the VAF specified in the QAPP (Tetra Tech, 2010b)³⁷.

Unless building-specific VAFs were available, a VAF of 0.1 is considered a very conservative assumption because VAFs can range from 0.1 to 0.0001 (or more) depending on groundwater-specific/soil-specific/building-specific characteristics (USEPA, 2008a). The larger the attenuation factor, the greater the potential concentration assumed to be present in indoor air for a given concentration in soil gas. Data from VI site investigations completed at two demonstration sites near Hill AFB and Altus AFB showed that there was significant uncertainty in the calculated subsurface-to-indoor air attenuation factors, with the standard deviation for the calculated values similar to or greater than the calculated attenuation factor values. Despite this variability, the calculated attenuation factors were consistently less than the USEPA default values. Measured sub-slab to indoor air attenuation factors ranged from 3.8E-04 to 7.6E-03 compared to the USEPA default value of 0.1 (McHugh and Nickels, 2008). Therefore, the use of a 0.1 VAF likely overestimated the predicted concentrations in indoor air and the actual risk associated with VI, especially for samples that were collected near-slab (versus sub-slab). However, for this screening assessment it was not appropriate to develop default VAFs that might be less conservative because of the documented variability in VAFs (USEPA, 2008a; McHugh and Nickels, 2008), the lack of groundwater-specific/soil-specific/building-specific characteristics for Naples, and the potential for increased VI migration (i.e. higher VAFs) over the long term as a result of natural (earthquake) or anthropogenic impacts to buildings. There is also potential for decreased VI impacts, though without collecting additional information (e.g., tap water, soil gas, and indoor air samples) and knowledge about potential sources, it was necessary to err towards conservatism rather than underestimate the risk.

The EPC within the building is another uncertainty associated with the VAF used to estimate concentrations in indoor air. For this SRE, except where site-specific building information was available, risks were calculated assuming that all USN Personnel lived on the first floor of a building (i.e., closest to the source). This assumption clearly did not apply to all residential properties sampled as part of this evaluation. The predicted indoor air concentrations and calculated risks were overestimated for USN Personnel living on the upper levels of a residence.

³⁷A VAF of 0.1 was applied in all instances to evaluate soil gas with the exception of multi-story residences that had a subsurface ventilated garages or apartment-type dwellings where the resident lived above the ground floor of the structure (i.e., the resident lived on the second floor or higher, assuming that the first floor was the ground floor of the building). In these instances a multi-story attenuation factor, assessed and supplied by Tetra Tech NUS, was applied as described in Appendix B.

5.5 Step-Out Sampling Data Gaps

There were data gaps associated with the Step-Out Sampling Event described in Section 2.1.1³⁸. Essentially, this approach was implemented to determine whether or not an area of contamination existed that might have impacted a number of residences within an area. This approach was successfully implemented during Phase I, which identified³⁹ an area of contamination with elevated concentrations of tetrachloroethene in groundwater⁴⁰ located in Study Area 8.

During Phase II of the PHE, 32 residences were identified throughout the nine study areas as having Unacceptable risk due to potential VI. As per the CNREURAFSWA decision, the Step-Out Sampling Event was discontinued and no additional residences have been sampled in the vicinity of these 32 residences to date. This decision was made based on the lack of information regarding subsurface sources, the wide variability of single soil gas sampling results, and to allow time to review the data collected in order to better assess recommendations presented in Volume II and to focus resources appropriately. Therefore, it is not possible to determine whether or not the multiple residences located in the vicinity of a residence that had an Unacceptable risk would also have Unacceptable risks associated with COPCs in the same media. This uncertainty is confounded by the fact that there was typically only one sampling event for tap water, soil, and soil gas from a residence and it was not technically defensible to assert that concentrations from a single event and single geographic location were applicable to a wider area.

5.6 Conceptual Site Model and Exposure Assumptions

The CSM for the SRE was developed for potentially-exposed populations living and working in the nine study areas. The model and subsequent exposure assumptions were developed for USN Personnel and associated support groups, which did not include Italian citizens, private citizens and their families, and other, non-Italian, foreign nationals. The RSLs used in this assessment for evaluating all locations (residences and U.S. Government-related facilities) were based on standard USEPA 30-year residential exposures. These RSLs were very conservative because the typical USN tour length is three years or occasionally six years. Consequently, the RSLs were five or 10 times more protective for individuals residing or working in Naples for six or three years, respectively. The USN decided to apply the more conservative RSLs in the SRE because in some instances DoDDS personnel and other U.S. civil servants remain in Campania for 10 to 20 years or more. Therefore, in order to be protective of the entire USN

³⁸In the U.S., it is common practice to utilize step-out sampling in environmental investigations to determine the extent of contamination in a geographic area where a contaminant source is documented and under investigation. This method selects sampling locations a specific distance (potentially in all directions) from the initial location where there is identified contamination, with the goal of determining the extent of contamination. For the PHE, if there was contamination in the Step-Out samples attributable to the same constituent that was responsible for "triggering" the Step-Out investigation, field personnel collected subsequent rounds of Step-Out samples further from the original sampling location until sample results were Acceptable.

³⁹An area of contaminated groundwater was identified; however, the full footprint of the impacted area is not known. In order to clearly define the impacted area, an investigation of the nature and extent of contamination in this area involving the installation of monitoring wells, et cetera would need to be performed by the appropriate Italian regulatory agencies because the USN does not have jurisdiction to perform this type of investigation. The USN can only collect tap water, soil, soil gas, and ambient air samples from residences that are leased through the USN, Naples, Italy Housing Office and where the tenant and landlord consent to sampling.

⁴⁰Determined from tap water samples during the PHE.

Personnel in the Campania Region, the 30-year RSLs were used, which overestimated the risks to the vast majority of the USN Personnel (approximately 90%) who live in Campania less than six years.

A source of uncertainty that resulted in an underestimation of the risk was that the dermal contact with tap water while bathing (i.e., showering or bathing) exposure pathway was not included in the evaluation. Since the SRE is a screening assessment, the USN decided to use standard USEPA RSLs. The USEPA RSLs for tap water do not include dermal contact with tap water while bathing exposure pathway, which resulted in an underestimation of the risks.

Another related source of uncertainty that resulted in an underestimation of the risk was that the incidental ingestion of tap water while bathing exposure pathway was not included in the evaluation. The tap water (via inhalation-only) pathway was based on the assumption that residents were using bottled water (as per the Advisory) and were not exposed to constituents in tap water through ingestion. However, the impact of this uncertainty on the risk assessment was diminished by including the potential ingestion of microorganisms in the inhalation-only pathway. Although microorganisms were not of concern via inhalation, they were evaluated for all tap water pathways in comparison to USMCLs to address the specific concern of incidental ingestion during showering and bathing, especially for infants and young children.

5.7 Toxicity Values

USEPA cancer and noncancer toxicity values were used to evaluate the potential cancer risks and noncancer hazards associated with exposure to constituents. The uncertainty associated with these toxicity values was addressed by the conservative (risk-adverse) assumptions and uncertainty factors included in the cancer and noncancer toxicity values estimated by the USEPA.

The toxicity values that were used to calculate risks were based on USEPA cancer guidelines that predated the *USEPA Guidelines for Carcinogenic Risk Assessment* (USEPA, 2005). Prior to 2005, the mechanism for carcinogenesis was always considered to be a “non-threshold” process, in which exposure to a carcinogen was considered to pose a small, but finite probability of generating a carcinogenic (cancer) response. Because risk at low exposure levels cannot usually be measured directly by animal experiments or by epidemiologic studies, a number of mathematical models and procedures were developed for use in extrapolating from high to low doses, which were most similar to potential human exposures from constituents in the environment. While different extrapolation models or procedures may reasonably fit the observed data, they may lead to large differences in the projected risk at low doses. In developing cancer slope factors (CSFs), the USEPA assumed that a single interaction with deoxyribonucleic acid (DNA) could initiate cancer. This linear extrapolation to zero exposure affects the slope of the extrapolation curve and therefore results in a more conservative (i.e., risk adverse) CSF. The procedure assumed that the relatively-high doses that were often used in animal studies can be extrapolated downward to extremely small doses, with some incremental risk of cancer always possible. It further assumed that even a small number of molecules (possibly a single molecule) of a carcinogen may cause changes in a single cell that could result in the cell dividing in an uncontrolled manner, eventually leading to cancer.

There is dispute as to whether or not linear extrapolation to zero is a valid approach because cells have a number of detoxification mechanisms (e.g., DNA repair enzymes) that can repair damage from carcinogens at low doses. Moreover, recent information demonstrates that some constituents cause cancer by other modes of action (e.g., by causing rapid proliferation of cells that increases the number of naturally-occurring mutations that result in an increased risk of cancer). USEPA's 2005 guidelines specifically state, "when adequate data on the mode of action provide sufficient evidence to support a nonlinear mode of action for the general population and/or subpopulations of concern, a different approach – a reference dose/reference concentration that assumes that nonlinearity – is used." (USEPA, 2005).

Prior to 2005, CSFs were usually derived by the USEPA using a linearized multistage model, and reflected the upper-bound limit of the cancer potency of any chemical. As a result, the calculated carcinogenic risk was likely to represent a plausible upper limit to the true risk. The actual risk is unknown, but was likely to be lower than the predicted risk, and may have been as low as zero (USEPA, 1989).

A noncancer reference dose (RfD) is defined as "an estimate (with uncertainty possibly spanning an order of magnitude or greater) of a daily exposure level for the human population, including sensitive subgroups, that is likely to be without an appreciable risk of deleterious effects during a portion of the lifetime" (USEPA, 1989). RfDs incorporate uncertainty factors, which represent a specific area of uncertainty inherent in the available data, such as:

- Differences in responsiveness between humans and animals in prolonged exposure studies (factor of up to 10; USEPA),
- Variation in susceptibility among individuals in the human population (factor of up to 10; USEPA), and
- Incomplete databases (e.g., those for which only the results of subchronic studies were available; factor of up to 10) (USEPA, 2008b).

In addition to the uncertainty factors, the USEPA applied modifying factors in some instances. Modifying factors range from one to 10 and were included to reflect a qualitative professional assessment of additional uncertainties in the critical study, and in the entire database, for the chemical not explicitly addressed by the uncertainty factors. The default value for the modifying factor is one.

The cumulative effect of these conservative assumptions used to derive toxicity values is more conservative (i.e., health-protective) risk estimates. In other words, the true hazard/risk is likely to be overstated.

5.8 Sensitivity Analyses

In risk assessment, a sensitivity analysis can be used to demonstrate the effect of changing a variable that falls within a range of uncertainties in order to evaluate the potential impact on risk management decisions. In this section, four factors were evaluated in terms of their impact on results and subsequent risk management decisions.

5.8.1 Changing the VAF from 0.1 to 0.01 for Phase II Residences Only

The VAF was a critical parameter in the evaluation of soil gas data and a sensitivity analysis was performed by modifying the VAF and recording the impact on the overall risk management decisions. The box presented below shows the results of changing the VAF from 0.1 to 0.01 for Phase II residences, which is within the range of generally accepted default VAFs. The box presented below shows that the total number of Phase II residences that would be Unacceptable for tap water (ingestion+inhalation), soil, and soil gas decreased from 88 to 67 when a VAF of 0.01 was used in the SRE. The total number of residences that would be Unacceptable for tap water (inhalation-only), soil, and soil gas decreased from 46 to 22 when a VAF of 0.01 was applied. The impact of changing the VAF decreased the number of residences categorized as Unacceptable by approximately 24% based on tap water (ingestion+inhalation), soil, and soil gas scenario and 52% based on tap water (inhalation-only), soil, and soil gas scenario.

Sensitivity Analysis of Changing the Vapor Attenuation Factor from 0.1 to 0.01

Sensitivity Analysis	Number of Unacceptable Residences Ingestion+Inhalation ¹	Number of Unacceptable Residences Inhalation Only ²
Base Case Evaluated in SRE (VAF = 0.1)	88	46
Changed VAF for Soil Gas from 0.1 to 0.01	67	22
Notes:		
¹ Ingestion+Inhalation exposure scenario for residences based on the total cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice.		
² Inhalation-Only exposure scenario for residences based on total cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice.		

5.8.2 Modifying the Exposure Duration from 30 Years to Six Years for Phase II Residences Only

The 30-year residential exposure duration was a critical parameter in the SRE and a sensitivity analysis was performed by modifying the exposure duration and recording the impact on the overall risk management decisions. The box presented below presents the results of changing the exposure duration from 30-years to six-years for Phase II residences. The results show that the total number of residences that would be Unacceptable for tap water (via ingestion+inhalation), soil, and soil gas decreased from 88 to 73 using the six-year exposure duration. The total number of residences that would be Unacceptable for tap water (via Inhalation-only), soil, and soil gas decreased from 46 to 24 when using the six-year exposure duration. The impact of changing the exposure duration to the shorter period would decrease the number of Unacceptable residences by approximately 17% based on tap water (ingestion+inhalation), soil, and soil gas scenario and 48% based on tap water (inhalation-only), soil, and soil gas scenario.

Sensitivity Analysis of Changing the Exposure Duration from 30 Years to Six Years for Phase II Residences Only

Sensitivity Analysis	Number of Unacceptable Residences Ingestion+Inhalation ¹	Number of Unacceptable Residences Inhalation Only ²
Base Case Evaluated in SRE (Exposure Duration = 30 Years)	88	46
Changed Exposure Duration from 30 Years to Six Years	73	24
Notes: ¹ Ingestion+Inhalation exposure scenario for residences based on the Total Cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice. ² Inhalation-Only exposure scenario for residences based on the Total Cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice.		

5.8.3 Changing the VAF from 0.1 to 0.01 and Modifying the Exposure Duration from 30 Years to Six Years for Phase II Residences Only

The box presented below shows the results of changing the VAF from 0.1 to 0.01 and changing the exposure duration from 30-years to six-years for Phase II residences. The results show that the total number of residences that would be Unacceptable for tap water (via ingestion+inhalation), soil, and soil gas decreased from 88 to 64 when using a VAF of 0.01 and a six-year exposure duration. The total number of residences that would be Unacceptable for tap water (via inhalation-only), soil, and soil gas decreased from 46 to 18 when using a VAF of 0.01 and the six-year exposure duration. The impact of changing the VAF to 0.01 and the exposure duration to the shorter period would decrease the number of Unacceptable residences by approximately 27% based on tap water (ingestion+inhalation), soil, and soil gas scenario and 61% based on tap water (inhalation-only), soil, and soil gas scenario.

Sensitivity Analysis of Changing the VAF from 0.1 to 0.01 and Changing the Exposure Duration from 30 Years to Six Years for Phase II Residences Only

Sensitivity Analysis	Number of Unacceptable Residences Ingestion+Inhalation ¹	Number of Unacceptable Residences Inhalation Only ²
Base Case Evaluated in SRE (VAF = 0.1 & Exposure Duration = 30 Years)	88	46
Changed VAF from 0.1 to 0.01 & Changed Exposure Duration from 30 Years to Six Years	64	18
Notes:		
¹ Ingestion+Inhalation exposure scenario for residences based on the Total Cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice.		
² Inhalation-Only exposure scenario for residences based on the Total Cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice.		

5.8.4 Removing the Multi-Story VAF for Phase II Residences Only

The box presented below shows the results of removing the multi-story VAFs from the risk calculations. Multi-story VAFs were incorporated into the soil gas risk calculations if a residence had a subsurface ventilated garage or apartment-type dwelling where the resident lived above the ground floor of the structure (i.e., the resident lived on the second floor or higher, assuming that the first floor is the ground floor of the building)⁴¹. The purpose of this sensitivity analysis is to present the spatial distribution of locations where subsurface contamination in soil and/or groundwater (that could adversely impact indoor air concentrations) may be located throughout study areas and the impact that the multi-story VAFs have on total risk calculations. Figure 4-30 presents soil gas cumulative risk results without the use of the multi-story VAF for Phase II residences. The total number of residences that would be Unacceptable for soil gas increases from 32 to 55 when the multi-story VAF is not included in the risk calculations. The total number of residences that would be Unacceptable for tap water (via ingestion+inhalation), soil, and soil gas increases from 88 to 105 when the multi-story VAF is not included in the risk calculations, see figure 4-30. The total number of residences that would be Unacceptable for tap water (via inhalation-only), soil, and soil gas increases from 46 to 69 when the multi-story VAF is not included in the risk calculations, see figure 4-31. The impact of removing the multi-story VAF would increase the number of Unacceptable residence by approximately 19% based on tap water (ingestion+inhalation), soil, and soil gas scenario and 50% based on tap water (inhalation-only), soil, and soil gas scenario.

Sensitivity Analysis of Removing the Multi-Story VAF for Phase II Residences Only⁴²

Sensitivity Analysis	Number of Unacceptable Residences based on Soil Gas Only	Number of Unacceptable Residences Ingestion+Inhalation ¹	Number of Unacceptable Residences Inhalation Only ²
Base Case Evaluated in SRE (VAF = 0.1, Exposure Duration = 30 Years, & Multi-Story VAF Applied)	32	88	46
Removed Multi-Story VAF from Soil Gas Risk Calculation	55	105	69
Notes:			
¹ Ingestion+Inhalation exposure scenario for residences based on the Total Cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice.			
² Inhalation-Only exposure scenario for residences based on the Total Cumulative EF-for tap water, soil, and soil gas, assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice.			

⁴¹ Multi-story attenuation factors were assessed and supplied by Tetra Tech NUS, as described in Appendix B.

⁴² Multi-story VAFs only apply to Phase II locations, see Table 4-3.

Table 2-1: Number of Residences Sampled by Study Area and by Sampling Event

Sampling Event	Study Area 1	Study Area 2	Study Area 3	Study Area 4	Study Area 5	Study Area 6	Study Area 7	Study Area 8	Study Area 9	Total
Phase I	21	8	5	3	32	13	7	39	2	130
Pre-Lease	83	6	2	4	63	27	17	37	1	240
500 Ft Step-Out	0	0	0	0	0	0	0	11	0	11
1,500 Ft Step-Out	0	0	0	0	0	0	0	25	0	25
Phase II	30	22	14	14	33	30	24	34	8	209
Total:	134	36	21	21	128	70	48	146	11	615

Notes:

Six hundred fifteen samples were collected from 543 residences during the PHE. Seventy-two of the residences were sampled (and re-sampled) during multiple sampling events (for a total of 615 samples). In most cases, the 72 residences were only re-sampled for media that were not sampled during previous sampling events.

Table 2-2: Number of Samples Collected by Medium at U.S. Government-Related Facilities

Facility (Study Area)	Tap Water		Irrigation Water		Soil		Soil Gas ²		Indoor Air		Ambient Air ³	
	Phase I	Phase II	Phase I	Phase II	Phase I	Phase II	Phase I	Phase II	Phase I	Phase II	Phase I	Phase II

Total Number of Collected Samples:	81	0	13	0	79	0	45	44	0	6	40	460

Notes:
¹This facility is located in Study Area 1 but was used to evaluate ambient air in Study Area 4.

²All shallow soil gas samples collected during Phase I were passive soil gas samples (i.e., Gore-Sorber® samples). Phase II shallow and sub-slab soil gas samples were collected using SUMMA canisters in accordance with USEPA Method TO-15.

³Number of samples collected for ambient air are approximate because not all analytical classes (e.g., SVOCs, VOCs, pesticides, etc.) were analyzed in every sample. Approximately five ambient air samples were collected from the U.S. Government-leased Villa in Study Area 8 during Phase I. Approximately 45 air samples were collected from the U.S. Government-leased Villa in Area 8 during Phase II.

Table 2-3: 2,3,7,8-Tetrachlorodibenzo-p-dioxin Toxicity Equivalency Factors

CAS Number	Constituent	2,3,7,8-TCDD Toxicity Equivalency Factor

Notes:

-- = Constituent was not detected

¹Inconsistencies between the results obtained from two methods (TO-13A and TO-15 for naphthalene and TO-11 and TO-15 for acetaldehyde) led to further research and Tetra Tech determined that the active soil gas (and select ambient air) data for naphthalene and acetaldehyde analyzed by the USEPA Method TO-15 were not suitable for inclusion in the Screening Risk Evaluation. See Section 2.1.

Notes:

-- = Constituent was not detected at this location.

Shaded cells indicate where the exposure point concentration exceeded the 2007 USEPA Air Toxics Ambient Air Concentration
⁽¹⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level was, "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

⁽²⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level was, "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdatamart/index.htm>.

⁽³⁾ This facility is located within Study Area 1 but data collected from this facility was used to evaluate air for Study Area 4.

⁽⁴⁾ Trans-1,4-Dichloro-2-Butene was only detected in 1 of 52 (1.92%) samples analyzed in Study Area 5 and was only detected in 1 of 455 (0.2%) ambient air samples from all nine study areas. The single detection was observed in a sample from residence #1756 located on the Italian economy and is not considered representative of the ambient air in Study Area 5. Therefore, trans-1,4-dichloro-2-butene was not evaluated further in the SRE for exposures associated with ambient air.

Notes:

0.0 = Value is less than 0.1

-- = Value is zero or samples were not collected for that medium

Inh. - Inhalation

Ing. - Ingestion

Shaded cells indicate residence is Unacceptable based on

⁽¹⁾ A vapor attenuation factor of 0.1 was applied in all instances to evaluate soil gas with the exception of multi-story residences that had a subsurface ventilated garages (i.e., podium-style construction) or apartment-type dwellings where the resident above the ground floor of the structure (i.e., the resident lived on the second floor or higher, assuming that the first floor is the ground floor of the building. In these instances a multi-story attenuation factor was applied as described in Appendix B

⁽²⁾ Ing.+Inh. exposure scenario for residences assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice

⁽³⁾ Inh. Only exposure scenario for residences assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice

⁽⁴⁾ Ing.+Inh. exposure scenario for residences (total cumulative exceedance factor based on tap water, soil, and soil gas) assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice.

⁽⁵⁾ Inh. Only exposure scenario for residences (total cumulative exceedance factor based on tap water, soil, and soil gas) assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice.

⁽⁶⁾ Excluding constituents that are present at concentrations similar to those found in the environment (e.g., inorganic elements except for lead, copper, and thallium)

⁽⁷⁾ For explanation of the Risk Management Categories see Section 4.3.

⁽⁸⁾ Residence is located outside of study area boundaries. It was included with the study area it was nearest to for analyses purposes.

Notes:

¹For explanation on the PHE Risk Management Categories, see Section 4.3

²An NCEF of one is equivalent to a hazard index of one

³A CEF of 10 is equivalent to a cancer risk of 1x10⁻⁵ or one in 100,000

⁴Media that have a CNCEF greater than one or a CCEF greater than 10, or tap water concentrations that exceed the USMCL

⁵Constituents that have exceedance factors greater than one (i.e., concentration was greater than RSL)

⁶Assuming that tap water IS used for drinking, cooking, brushing teeth, and making ice

⁷Assuming that tap water IS NOT used for drinking, cooking, brushing teeth, and making ice

⁸Exceedance of chemical or microorganism USMCL

⁹Exceedance of microorganism USMCLs only

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdata/mart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

⁽¹⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdata/mart/index.htm>.

⁽²⁾ EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

⁽³⁾ This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

⁽⁴⁾ These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

⁽⁵⁾ These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

Notes:

-- = Constituent was not detected at this location.

Shaded and bold values are instances where the EPC is greater than the RSL

(1) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Data was obtained for 2007 USEPA Air Toxics Database: San Diego County, California; Los Angeles County, California; King County (Seattle), Washington; Harris County (Houston), Texas; Ellis County (Midlothian), Texas; Washington DC. <https://www.epa.gov/ttn/airs/aqsdata/mart/index.htm>.

(2) EPC was based on the 95% upper confidence limit on the mean where the underlying distribution, at 5% significance level, was "Normal" or "Undetermined"; logarithmic 95% upper confidence limit on the logarithmic mean where the underlying distribution, at 5% significance level, was "Lognormal" -- and capped at the maximum detected concentration. Ambient air data collected as part of the year-long ambient air monitoring study (06/01/2008 - 07/08/2009).

(3) This facility is located in Study Area 1 but used to evaluate ambient air in Study Area 4.

(4) These results are not directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was included in these CCEF/CNCEF calculations. Consequently, it is not possible to determine if the ambient air risks in Naples are truly higher than the risks based on the 2007 USEPA Air Toxics database.

(5) These results are directly comparable between Naples and the United States because the CEFs/NCEFs for COPCs that were detected in ambient air in Naples but were not available in the 2007 USEPA Air Toxics Database, were not included in the CCEF/CNCEF calculations. For example, 1,2-dibromo-3-chloropropane was detected in ambient air in Naples and was responsible for approximately 80% of the CCEF but was not available in the 2007 USEPA Air Toxics Database. It was not included in these CCEF/CNCEF calculations.

RISK-BASED SCREENING LEVELS

1.1 RSL Overview

To determine whether or not the sampling results for soil, soil gas, and tap water are potentially of concern to human health, the sampling results were compared to United States Environmental Protection Agency (USEPA) risk-based regional screening levels (RSLs) (USEPA, 2009). The RSLs incorporate many conservative assumptions about exposure to be protective of human health. The detailed calculations are presented in the USEPA RSL User's Guide which is included in this appendix as Attachment A-1.

The USEPA RSLs are calculated based on carcinogenic (i.e., cancer) risks and noncarcinogenic (i.e., noncancer) health effects. Cancer risk is an estimate of how exposure to a chemical may increase the normal or expected rate of developing cancer in a population of people. The USEPA generally evaluates cancer risk as follows:

- **Acceptable Risk** – A cancer risk of 1×10^{-6} (i.e., one person out of 1,000,000 will develop cancer) or less is considered safe (i.e., acceptable). Note: The USEPA generally also considers the range between one in 10,000 (1×10^{-4}) and one in 1,000,000 (1×10^{-6}) people as a safe (i.e., acceptable) range, and actions to reduce the risk may or may not be required based on various site-specific factors. The USEPA typically considers additional actions to reduce cancer risks that are close to or greater than one in 10,000 (1×10^{-4}) people.
- **Unacceptable Risk** – USEPA considers an increase of “more than” one additional case of cancer (or greater) in 10,000 (1×10^{-4}) people to be of concern (i.e., unacceptable).

Noncancer health effects are expressed by a number known as the “hazard quotient” or “HQ.” The HQ compares the amount of a chemical that people may have been exposed to over a specified time period with the amount that is considered to have no effect (i.e., safe). If people are exposed to an amount greater than that considered safe for a particular chemical, then the ratio will be greater than one. Because people can be exposed to more than one chemical at a time, the HQs for different chemicals are added together to give an overall “hazard index” or “HI,” unless data is available to indicate that they should not be added together. USEPA policy considers chemical concentrations resulting in an HI above one to be of concern for developing potential noncancer health effects. Professional judgment must be used to evaluate the potential noncancer health effects related to the concentration of these chemicals to determine if actions to reduce the risk are needed.

- FAQ
- Equations
- Calculator
- Generic Tables

This guidance sets forth a recommended, but not mandatory, approach based upon currently available information with respect to risk assessment for response actions at CERCLA sites. This document does not establish binding rules. Alternative approaches for risk assessment may be found to be more appropriate at specific sites (e.g., where site circumstances do not match the underlying assumptions, conditions and models of the guidance). The decision whether to use an alternative approach and a description of any such approach should be documented for such sites. Accordingly, when comments are received at individual CERCLA sites questioning the use of the approaches recommended in this guidance, the comments should be considered and an explanation provided for the selected approach.

It should also be noted that the screening levels (SLs) in these tables are based upon human health risk and do not address potential ecological risk. Some sites in sensitive ecological settings may also need to be evaluated for potential ecological risk. EPA's guidance "Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessment" <http://www.epa.gov/oswer/riskassessment/ecorisk/ecorisk.htm> contains an eight step process for using benchmarks for ecological effects in the remedy selection process.

1. Introduction

The purpose of this website is to provide default screening tables and a calculator to assist Remedial Project Managers (RPMs), On Scene Coordinators (OSC's), risk assessors and others involved in decision-making concerning CERCLA hazardous waste sites and to determine whether levels of contamination found at the site may warrant further investigation or site cleanup, or whether no further investigation or action may be required.

Users within and outside the CERCLA program should use the tables or calculator results at their own discretion and they should take care to understand the assumptions incorporated in these results and to apply the SLs appropriately.

The SLs presented in the Generic Tables are chemical-specific concentrations for individual contaminants in air, drinking water and soil that may warrant further investigation or site cleanup. The SLs generated from the calculator may be site-specific concentrations for individual chemicals in soil, air, water and fish. **It should be emphasized that SLs are not cleanup standards.** SLs should not be used as cleanup levels for a CERCLA site until the other remedy selections identified in the relevant portions of the National Contingency Plan (NCP), 40 CFR Part 300, have been evaluated and considered. PRGs is a term used to describe a project team's early and evolving identification of possible remedial goals. PRGs may be initially identified early in the Remedial Investigation/ Feasibility Study (RI/FS) process (e.g., at RI scoping) to select appropriate detection limits for RI sampling. Typically, it is necessary for PRGs to be more generic early in the process and to become more refined and site-specific as data collection and assessment progress. The SLs identified on this website are likely to serve as PRGs early in the process--e.g., at RI scoping and at screening of chemicals of potential concern (COPCs) for the baseline risk assessment. However, once the baseline risk assessment has been performed, PRGs can be derived from the calculator using site-specific risks, and the SLs in the Generic Tables are less likely to apply. PRGs developed in the FS will usually be based on site-specific risks and Applicable or Relevant and Appropriate Requirements (ARARs) and not on generic SLs.

2. Understanding the Screening Tables

2.1 General Considerations

Risk-based SLs are derived from equations combining exposure assumptions with chemical-specific toxicity values.

2.2 Exposure Assumptions

Generic SLs are based on default exposure parameters and factors that represent Reasonable Maximum Exposure (RME) conditions for long-term/chronic exposures and are based on the methods outlined in EPA's [Risk Assessment Guidance for Superfund, Part B Manual \(1991\)](#) and Soil Screening Guidance documents (1996 and 2002).

Site-specific information may warrant modifying the default parameters in the equations and calculating site-specific SLs, which may differ from the values in these tables. In completing such calculations, the user should answer some fundamental questions about the site. For example, information is needed on the contaminants detected at the site, the land use, impacted media and the likely pathways for human exposure.

Whether these generic SLs or site-specific screening levels are used, it is important to clearly demonstrate the equations and exposure parameters used in deriving SLs at a site. A discussion of the assumptions used in the SL calculations should be included in the documentation for a CERCLA site.

2.3 Toxicity Values

In 2003, EPA's Superfund program revised its hierarchy of human health toxicity values, providing three tiers of toxicity values (<http://www.epa.gov/oswer/riskassessment/pdf/hhmemo.pdf>). Three tier 3 sources were identified in that guidance, but it was acknowledged that additional tier 3 sources may exist. The 2003 guidance did not attempt to rank or put the identified tier 3 sources into a hierarchy of their own. However, when developing the screening tables and calculator presented on this website, EPA needed to establish a hierarchy among the tier 3 sources. The toxicity values used as "defaults" in these tables and calculator are consistent with the 2003 guidance. Toxicity values from the following sources in the order in which they are presented below are used as the defaults in these tables and calculator.

1. EPA's Integrated Risk Information System (IRIS)
2. The Provisional Peer Reviewed Toxicity Values (PPRTVs) derived by EPA's Superfund Health Risk Technical Support Center (STSC) for the EPA Superfund program. (Note that the PPRTV website is not open to users outside of EPA, but assessments can be obtained for use on Superfund sites by contacting Dave Crawford at Crawford.Dave@epa.gov).
3. The Agency for Toxic Substances and Disease Registry (ATSDR) minimal risk levels (MRLs)

- The California Environmental Protection Agency/Office of Environmental Health Hazard Assessment's toxicity values (<http://www.oehha.ca.gov/risk/ChemicalDB/index.asp>)
- The EPA Superfund program's Health Effects Assessment Summary. (Note that the [HEAST](#) website of toxicity values for chemical contaminants is not open to users outside of EPA, but values can be obtained for use on Superfund sites by contacting Dave Crawford at Crawford.Dave@epa.gov).

Users of these screening tables and calculator wishing to consider using other toxicity values, including toxicity values from additional sources, may find the discussions and seven preferences on selecting toxicity values in the attached Environmental Council of States paper useful for this purpose ([ECOS website](#), ECOS paper).

When using toxicity values, users are encouraged to carefully review the basis for the value and to document the basis of toxicity values used on a CERCLA site.

2.3.1 Reference Doses

The current, or recently completed, EPA toxicity assessments used in these screening tables (IRIS and PPRTVs) define a reference dose, or RfD, as an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. It can be derived from a NOAEL, LOAEL, or benchmark dose, or using categorical regression, with uncertainty factors generally applied to reflect limitations of the data used. RfDs are generally the toxicity value used most often in evaluating noncancer health effects at Superfund sites. Various types of RfDs are available depending on the critical effect (developmental or other) and the length of exposure being evaluated (chronic or subchronic). Some of the SLs in these tables also use Agency for Toxic Substances and Disease Registry (ATSDR) chronic oral minimal risk levels (MRLs) as an oral chronic RfD. The HEAST RfDs used in these SLs were based upon then current EPA toxicity methodologies, but did not use the more recent benchmark dose or categorical regression methodologies. Chronic oral reference doses and ATSDR chronic oral MRLs are expressed in units of (mg/kg-day).

Chronic oral RfDs are specifically developed to be protective for long-term exposure to a compound. As a guideline for Superfund program risk assessments, chronic oral RfDs generally should be used to evaluate the potential noncarcinogenic effects associated with exposure periods greater than 7 years (approximately 10 percent of a human lifetime). However, this is not a bright line. Note, that ATSDR defines chronic exposure as greater than 1 year for use of their values.

2.3.2 Reference Concentrations

The current, or recently completed, EPA toxicity assessments used in these screening tables (IRIS and PPRTV assessments) define a reference concentration (RfC) as an estimate (with uncertainty spanning perhaps an order of magnitude) of a continuous inhalation exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime. It can be derived from a NOAEL, LOAEL, or benchmark concentration, or using categorical regression with uncertainty factors generally applied to reflect limitations of the data used. Various types of RfCs are available depending on the critical effect (developmental or other) and the length of exposure being evaluated (chronic or subchronic). These screening tables also use ATSDR chronic inhalation MRLs as a chronic RfC, intermediate inhalation MRLs as a subchronic RfC and California Environmental Protection Agency (chronic) Reference Exposure Levels (RELs) as chronic RfCs. These screening tables may also use some RfCs from EPA's HEAST tables.

The chronic inhalation reference concentration is generally used for continuous or near continuous inhalation exposures that occur for 7 years or more. However, this is not a bright line, and ATSDR chronic MRLs are based on exposures longer than 1 year. EPA chronic inhalation reference concentrations are expressed in units of (mg/m³). Cal EPA RELs are presented in µg/m³ and have been converted to mg/m³ for use in these screening tables. Some ATSDR inhalation MRLs are derived in parts per million (ppm) and some in mg/m³. For use in this table all were converted into mg/m³.

2.3.3 Slope Factors

A slope factor and the accompanying weight-of-evidence determination are the toxicity data most commonly used to evaluate potential human carcinogenic risks. Generally, the slope factor is a plausible upper-bound estimate of the probability of a response per unit intake of a chemical over a lifetime. The slope factor is used in risk assessments to estimate an upper-bound lifetime probability of an individual developing cancer as a result of exposure to a particular level of a potential carcinogen. Slope factors should always be accompanied by the weight-of-evidence classification to indicate the strength of the evidence that the agent is a human carcinogen.

Oral slope factors are toxicity values for evaluating the probability of an individual developing cancer from oral exposure to contaminant levels over a lifetime. Oral slope factors are expressed in units of (mg/kg-day)⁻¹. When available, oral slope factors from EPA's IRIS or PPRTV assessments are used. The ATSDR does not derive cancer toxicity values (e.g. slope factors or inhalation unit risks). Some oral slope factors used in these screening tables were derived by the California Environmental Protection Agency, whose methodologies are quite similar to those used by EPA's IRIS and PPRTV assessments. When oral slope factors are not available in IRIS, PPRTV or Cal EPA assessments, values from HEAST are used.

2.3.4 Inhalation Unit Risk

The IUR is defined as the upper-bound excess lifetime cancer risk estimated to result from continuous exposure to an agent at a concentration of 1 µg/m³ in air. Inhalation unit risk toxicity values are expressed in units of (mg/m³)⁻¹.

When available, inhalation unit risk values from EPA's IRIS or PPRTV assessments are used. The ATSDR does not derive cancer toxicity values (e.g. slope factors or inhalation unit risks). Some inhalation unit risk values used in these screening tables were derived by the California Environmental Protection Agency, whose methodologies are quite similar to those used by EPA's IRIS and PPRTV assessments. When inhalation unit risk values are not available in IRIS, PPRTV or Cal EPA assessments, values from HEAST are used.

2.3.5 Toxicity Equivalence Factors

Some chemicals are members of the same family and exhibit similar toxicological properties; however, they differ in the degree of toxicity. Therefore, a toxicity equivalence factor (TEF) must first be applied to adjust the measured concentrations to a toxicity equivalent concentration.

The following table contains the various dioxin-like toxicity equivalency factors for Dioxins, Furans and PCBs (Van den Berg et al. (2006)), which are the World Health Organization 2005 values.

Dioxin Toxicity Equivalence Factors

	Dioxins and Furans	TEF
Chlorinated dibenzo-p-dioxins		
	2,3,7,8-TCDD	1

	1,2,3,7,8-PeCDD	1	
	1,2,3,4,7,8-HxCDD	0.1	
	1,2,3,6,7,8-HxCDD	0.1	
	1,2,3,7,8,9-HxCDD	0.1	
	1,2,3,4,6,7,8-HpCDD	0.01	
	OCDD	0.0003	
Chlorinated dibenzofurans			
	2,3,7,8-TCDF	0.1	
	1,2,3,7,8-PeCDF	0.03	
	2,3,4,7,8-PeCDF	0.3	
	1,2,3,4,7,8-HxCDF	0.1	
	1,2,3,6,7,8-HxCDF	0.1	
	1,2,3,7,8,9-HxCDF	0.1	
	2,3,4,6,7,8-HxCDF	0.1	
	1,2,3,4,6,7,8-HpCDF	0.01	
	1,2,3,4,7,8,9-HpCDF	0.01	
	OCDF	0.0003	
PCBs			
	IUPAC No.	Structure	
Non-ortho	77	3,3',4,4'-TetraCB	0.0001
	81	3,4,4',5'-TetraCB	0.0003
	126	3,3',4,4',5'-PeCB	0.1
	169	3,3',4,4',5,5'-HxCB	0.03
Mono-ortho	105	2,3,3',4,4'-PeCB	0.00003
	114	2,3,4,4',5'-PeCB	0.00003
	118	2,3',4,4',5'-PeCB	0.00003
	123	2',3,4,4',5'-PeCB	0.00003
	156	2,3,3',4,4',5'-HxCB	0.00003
	157	2,3,3',4,4',5'-HxCB	0.00003
	167	2,3',4,4',5,5'-HxCB	0.00003
	189	2,3,3',4,4',5,5'-HpCB	0.00003
Di-ortho*	170	2,2',3,3',4,4',5'-HpCB	0.0001
	180	2,2',3,4,4',5,5'-HpCB	0.00001

* Di-ortho values come from Ahlborg, U.G., et al. (1994), which are the WHO 1994 values from Toxic equivalency factors for dioxin-like PCBs: Report on WHO-ECEH and IPCS consultation, December 1993 Chemosphere, Volume 28, Issue 6, March 1994, Pages 1049-1067.

Carcinogenic polycyclic aromatic hydrocarbons

Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons (EPA/600/R-93/089, July 1993), recommends that a toxicity equivalency factor (TEF) be used to convert concentrations of carcinogenic polycyclic aromatic hydrocarbons (cPAHs) to an equivalent concentration of benzo(a)pyrene when assessing the risks posed by these substances. These TEFs are based on the potency of each compound relative to that of benzo(a)pyrene. For the toxicity value database, these TEFs have been applied to the toxicity values. Although this is not in complete agreement with the direction in the aforementioned documents, this approach was used so that toxicity values could be generated for each cPAH. Additionally, it should be noted that computationally it makes little difference whether the TEFs are applied to the concentrations of cPAHs found in environmental samples or to the toxicity values as long as the TEFs are not applied to both. However, if the adjusted toxicity values are used, the user will need to sum the risks from all cPAHs as part of the risk assessment to derive a total risk from all cPAHs. A total risk from all cPAHs is what is derived when the TEFs are applied to the environmental concentrations of cPAHs and not to the toxicity values.

The following table presents the TEFs for cPAHs recommended in *Provisional Guidance for Quantitative Risk Assessment of Polycyclic Aromatic Hydrocarbons*.

Toxicity Equivalency Factors for Carcinogenic Polycyclic Aromatic Hydrocarbons

Compound	TEF
Benzo(a)pyrene	1.0
Benz(a)anthracene	0.1
Benzo(b)fluoranthene	0.1
Benzo(k)fluoranthene	0.01
Chrysene	0.001
Dibenz(a,h)anthracene	1.0
Indeno(1,2,3-c,d)pyrene	0.1

2.4 Chemical-specific Parameters

Several chemical specific parameters are needed for development of the SLs. Different hierarchies are used for organic and inorganic compounds.

2.4.1 Organic Compounds

- Values were taken from <http://www.epa.gov/opptintr/exposure/pubs/episuite.htm>. These programs estimate various chemical-specific properties. The calculations for these SL tables use the experimental values for a property over the estimated values.
- EPA Soil Screening Level (SSL) Exhibit C-1.
- WATER8, which has been replaced with WATER9.
- Syracuse Research Corporation (SRC). 2005. CHEMFATE Database. SRC. Syracuse, NY. Accessed July 2005.

- Syracuse Research Corporation (SRC). 2005. PHYSPROP Database. SRC. Syracuse, NY. Accessed July 2005.

2.4.2 Inorganic Compounds

For unitless Henry's Law (ammonia, chlorine, cyanogen, cyanogen chloride, hydrogen cyanide only):

- WATER 9, (EPA 2001). See section 4.9.2.

3. Using the SL Tables

The "[Generic Tables](#)" page provides generic concentrations in the absence of site-specific exposure assessments. These concentrations can be used for:

- Prioritizing multiple sites or operable units or areas of concern within a facility or exposure units
- Setting risk-based detection limits for contaminants of potential concern (COPCs)
- Focusing future site investigation and risk assessment efforts (e.g., selecting COPCs for the baseline risk assessment)
- Identifying contamination which may warrant cleanup
- Identifying sites, or portions of sites, which warrant no further action or investigation
- Initial cleanup goals when site-specific data are lacking

Generic SLs are provided for multiple exposure pathways and for chemicals with both carcinogenic and noncarcinogenic effects. A Summary Table is provided that contains SLs corresponding to either a 10^{-6} risk level for carcinogens or a Hazard Quotient (HQ) of 1 for non-carcinogens. The summary table identifies whether the SL is based on cancer or noncancer effects by including a "c" or "n" after the SL. The Supporting Tables provide SLs corresponding to a 10^{-6} risk level for carcinogens and an HQ of 1 for noncarcinogens. Site specific SLs corresponding to an HQ of less than 1 may be appropriate for those sites where multiple chemicals are present that have RfDs or RfCs based on the same toxic endpoint. Site specific SLs based upon a cancer risk greater than 10^{-6} can be calculated and may be appropriate based upon site specific considerations. However, caution is recommended to ensure that cumulative cancer risk for all actual and potential carcinogenic contaminants found at the site does not have a residual (after site cleanup, or when it has been determined that no site cleanup is required) cancer risk exceeding 10^{-4} . Also, changing the target risk or HI may change the balance between the cancer and noncancer endpoints. At some concentrations, the cancer-risk concerns predominate; at other concentrations, noncancer-HI concerns predominate. The user must take care to consider both when adjusting target risks and hazards.

Tables are provided in either MS Excel or in PDF format. The following lists the tables provided and a description of what is contained in each:

- Summary Table - provides a list of contaminants, toxicity vales, MCLs and the lesser (more protective) of the cancer and noncancer SLs for resident soil, industrial soil, resident air, industrial air and tapwater.
- Residential Soil Supporting Table - provides a list of contaminants, toxicity vales and the cancer and noncancer SLs for resident soil.
- Industrial Soil Supporting Table - provides a list of contaminants, toxicity vales and the cancer and noncancer SLs for industrial soil.
- Residential Air Supporting Table - provides a list of contaminants, toxicity vales and the cancer and noncancer SLs for resident air.
- Industrial Air Supporting Table - provides a list of contaminants, toxicity vales and the cancer and noncancer SLs for industrial air.
- Residential Tapwater Supporting Table - provides a list of contaminants, toxicity vales, MCLs and the cancer and noncancer SLs for tapwater.

3.1 Developing a Conceptual Site Model

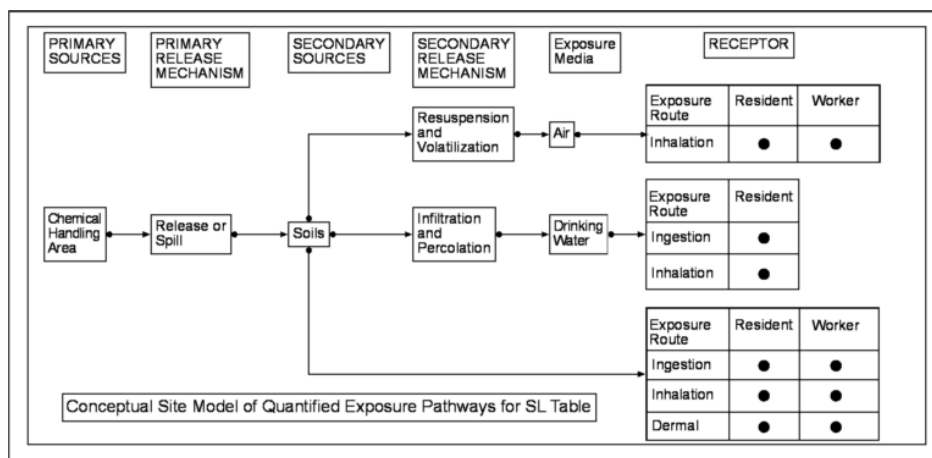

When using generic SLs at a site, the exposure pathways of concern and site conditions should match those used in developing the SLs presented here. (Note, however, that future uses may not match current uses. Future uses are potential site uses that may occur in the future. At Superfund sites, future uses should be considered as well as current uses. RAGS Part A, Chapter 6, provides guidance on selecting future-use receptors.) Thus, it is necessary to develop a conceptual site model (CSM) to identify likely contaminant source areas, exposure pathways, and potential receptors. This information can be used to determine the applicability of SLs at the site and the need for additional information. The final CSM diagram represents linkages among contaminant sources, release mechanisms, exposure pathways, and routes and receptors based on historical information. It summarizes the understanding of the contamination problem. A separate CSM for ecological receptors can be useful. Part 2 and Attachment A of the Soil Screening Guidance for Superfund: Users Guide (EPA 1996) contains the steps for developing a CSM.

As a final check, the CSM should address the following questions:

- Are there potential ecological concerns?
- Is there potential for land use other than those used in the SL calculations (i.e., residential and commercial/industrial)?
- Are there other likely human exposure pathways that were not considered in development of the SLs?
- Are there unusual site conditions (e.g. large areas of contamination, high fugitive dust levels, potential for indoor air contamination)?

The SLs and later PRGs may need to be adjusted to reflect the answers to these questions.

Below is a potential CSM of the quantified pathways addressed in the SL Tables.

3.2 Background

EPA may be concerned with two types of background at sites: naturally occurring and anthropogenic. Natural background is usually limited to metals whereas anthropogenic (i.e. human-made) "background" includes both organic and inorganic contaminants.

Please note that the SL tables, which are purely risk-based, may yield SLs lower than naturally occurring background concentrations of some chemicals in some areas. However, background considerations may be incorporated into the assessment and investigation of sites, as acknowledged in existing EPA guidance. Background levels should be addressed as they are for other contaminants at CERCLA sites. For further information see EPA's guidance [Role of Background in the CERCLA Cleanup Program \(PDF\)](#) (13 pp, 147K, [About PDF](#)), April 2002, (OSWER 9285.6-07P) and [Guidance for Comparing Background and Chemical Concentration in Soil for CERCLA Sites \(PDF\)](#) (89 pp, 126MB, [About PDF](#)), September 2002, (OSWER 9285.7-41).

Generally EPA does not clean up below natural background. In some cases, the predictive risk-based models generate SL concentrations that lie within or even below typical background concentrations for the same element or compound. Arsenic, aluminum, iron and manganese are common elements in soils that have background levels that may exceed risk-based SLs. This does not mean that these metals cannot be site-related, or that these metals should automatically be attributed to background. Attribution of chemicals to background is a site-specific decision; consult your regional risk assessor.

Where anthropogenic "background" levels exceed SLs and EPA has determined that a response action is necessary and feasible, EPA's goal will be to develop a comprehensive response to the widespread contamination. This will often require coordination with different authorities that have jurisdiction over the sources of contamination in the area.

3.3 Potential Problems

As with any risk based screening table or tool, the potential exists for misapplication. In most cases, this results from not understanding the intended use of the SLs or PRGs. In order to prevent misuse of the SLs, the following should be avoided:

- Applying SLs to a site without adequately developing a conceptual site model that identifies relevant exposure pathways and exposure scenarios.
- Not considering the effects from the presence of multiple contaminants, where appropriate.
- Use of the SLs as cleanup levels without adequate consideration of the other NCP remedy selection criteria on CERCLA sites.
- Use of SL as cleanup levels without verifying numbers with a toxicologist or regional risk assessor.
- Use of outdated SLs when tables have been superseded by more recent values.
- Not considering the effects of additivity when screening multiple chemicals.

- Applying inappropriate target risks or changing a cancer target risk without considering its effect on noncancer, or vice versa.
- Not performing additional screening for pathways not included in these SLs (e.g., vapor intrusion, fish consumption).
- Adjusting SLs upward by factors of 10 or 100 without consulting a toxicologist or regional risk assessor.

4. Technical Support Documentation

The SLs consider human exposure to individual contaminants in air, drinking water and soil. The equations and technical discussion are aimed at developing risk-based SLs or PRGs. The following text presents the land use equations and their exposure routes. Table 1 presents the definitions of the variables and their default values. Any alternative values or assumptions used in developing SLs on a site should be presented with supporting rationale in the decision document on CERCLA sites.

4.1 Residential Soil

4.1.1 Noncancer

The residential soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{res-sol-nc-ing} \text{ (mg/kg)} = \frac{THQ \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times ED_c \text{ (6 years)} \right) \times BW_c \text{ (15 Kg)}}{EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times ED_c \text{ (6 year)} \times \frac{1}{RfD_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)} \times IRS_c \left(\frac{200 \text{ mg}}{\text{day}} \right) \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}$$

- inhalation of particulates emitted from soil,

$$SL_{res-sol-nc-inh} \text{ (mg/kg)} = \frac{THQ \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times ED_c \text{ (6 years)} \right)}{EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times ED_c \text{ (6 year)} \times ET_{rs} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \frac{1}{RfC \left(\frac{\text{mg}}{\text{m}^3} \right)} \times \left(\frac{1}{Vf_s \left(\frac{\text{m}^3}{\text{Kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{Kg}} \right)} \right)}$$

- dermal contact with soil,

$$SL_{res-sol-nc-der} \text{ (mg/kg)} = \frac{THQ \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times ED_c \text{ (6 years)} \right) \times BW_c \text{ (15 Kg)}}{EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times ED_c \text{ (6 year)} \times \frac{1}{\left(RfD_o \left(\frac{\text{mg}}{\text{Kg-day}} \right) \times GIABS \right)} \times SA_c \left(\frac{2800 \text{ cm}^2}{\text{day}} \right) \times AF_c \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times ABS_d \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}$$

- Total.

$$SL_{res-sol-nc-tot} \text{ (mg/kg)} = \frac{1}{\frac{1}{SL_{res-sol-nc-ing}} + \frac{1}{SL_{res-sol-nc-der}} + \frac{1}{SL_{res-sol-nc-inh}}}$$

4.1.1 Carcinogenic

The residential soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{res-sol-ca-ing} \text{ (mg/kg)} = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{CSF_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)^{-1} \times EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times IFS_{adj} \left(\frac{114 \text{ mg-Year}}{\text{Kg-day}} \right) \times \left(\frac{10^{-6} \text{ Kg}}{\text{mg}} \right)}$$

where:

$$IFS_{adj} \left(\frac{114 \text{ mg-Year}}{\text{Kg-day}} \right) = \frac{ED_c \text{ (6 years)} \times IRS_c \left(\frac{200 \text{ mg}}{\text{day}} \right)}{BW_c \text{ (15 Kg)}} + \frac{ED_r - ED_c \text{ (24 years)} \times IRS_a \left(\frac{100 \text{ mg}}{\text{day}} \right)}{BW_a \text{ (70 Kg)}}$$

- inhalation of particulates emitted from soil,

$$SL_{res-sol-ca-inh} \text{ (mg/kg)} = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right) \times EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \left(\frac{1}{Vf_s \left(\frac{\text{m}^3}{\text{Kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{Kg}} \right)} \right) \times ED_r \text{ (30 years)} \times ET_{rs} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right)}$$

- dermal contact with soil,

$$SL_{res-sol-ca-der} \text{ (mg/kg)} = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{\left(\frac{CSF_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)^{-1}}{GIABS} \right) \times EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times DFS_{adj} \left(\frac{361 \text{ mg-Year}}{\text{Kg-day}} \right) \times ABS_d \times \left(\frac{10^{-6} \text{ Kg}}{\text{mg}} \right)}$$

where:

$$DFS_{adj} \left(\frac{361 \text{ mg-Year}}{\text{Kg-day}} \right) = \frac{ED_c \text{ (6 years)} \times SA_c \left(\frac{2800 \text{ cm}^2}{\text{day}} \right) \times AF_c \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right)}{BW_c \text{ (15 Kg)}} + \frac{ED_r-ED_c \text{ (24 years)} \times SA_a \left(\frac{5700 \text{ cm}^2}{\text{day}} \right) \times AF_a \left(\frac{0.07 \text{ mg}}{\text{cm}^2} \right)}{BW_a \text{ (70 Kg)}}$$

- Total.

$$SL_{res-sol-ca-tot} \text{ (mg/kg)} = \frac{1}{\frac{1}{SL_{res-sol-ca-ing}} + \frac{1}{SL_{res-sol-ca-der}} + \frac{1}{SL_{res-sol-ca-inh}}}$$

4.2.3 Mutagenic

The residential soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{res-sol-mu-ing} \text{ (mg/kg)} = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{CSF_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)^{-1} \times EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times IFSM_{adj} \left(\frac{489.5 \text{ mg-Year}}{\text{Kg-day}} \right) \times \left(\frac{10^{-6} \text{ Kg}}{\text{mg}} \right)}$$

where:

$$IFSM_{adj} \left(\frac{489.5 \text{ mg-Year}}{\text{Kg-day}} \right) = \frac{ED_{0-2} \text{ (yr)} \times IRS_c \left(\frac{200 \text{ mg}}{\text{day}} \right) \times 10}{BW_c \text{ (15 Kg)}} + \frac{ED_{2-6} \text{ (yr)} \times IRS_c \left(\frac{200 \text{ mg}}{\text{day}} \right) \times 3}{BW_c \text{ (15 Kg)}} + \frac{ED_{6-16} \text{ (yr)} \times IRS_a \left(\frac{100 \text{ mg}}{\text{day}} \right) \times 3}{BW_a \text{ (70 Kg)}} + \frac{ED_{16-30} \text{ (yr)} \times IRS_a \left(\frac{100 \text{ mg}}{\text{day}} \right) \times 1}{BW_a \text{ (70 Kg)}}$$

- inhalation of particulates emitted from soil,

$$SL_{res-sol-mu-inh} \text{ (mg/kg)} = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times ET_{rs} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right) \times \left(\frac{ED_{0-2} \text{ (yrs)} \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 10 + ED_{2-6} \text{ (yrs)} \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 3}{ED_{6-16} \text{ (yrs)} \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 3 + ED_{16-30} \text{ (yrs)} \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 1} \right) \times \left(\frac{1}{VF_s \left(\frac{\text{m}^3}{\text{Kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{Kg}} \right)} \right)}$$

- dermal contact with soil,

$$SL_{res-sol-mu-der} \text{ (mg/kg)} = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{\left(\frac{CSF_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)^{-1}}{GIABS} \right) \times EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times DFSM_{adj} \left(\frac{1445 \text{ mg-Year}}{\text{Kg-day}} \right) \times ABS_d \times \left(\frac{10^{-6} \text{ Kg}}{\text{mg}} \right)}$$

where:

$$DFSM_{adj} \left(\frac{1445 \text{ mg-Year}}{\text{Kg-day}} \right) = \frac{ED_{0-2} \text{ (yr)} \times AF_c \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times SA_c \left(\frac{2800 \text{ cm}^2}{\text{day}} \right) \times 10}{BW_c \text{ (15 Kg)}} + \frac{ED_{2-6} \text{ (yr)} \times AF_c \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times SA_c \left(\frac{2800 \text{ cm}^2}{\text{day}} \right) \times 3}{BW_c \text{ (15 Kg)}} + \frac{ED_{6-16} \text{ (yr)} \times AF_a \left(\frac{0.07 \text{ mg}}{\text{cm}^2} \right) \times SA_a \left(\frac{5700 \text{ cm}^2}{\text{day}} \right) \times 3}{BW_a \text{ (70 Kg)}} + \frac{ED_{16-30} \text{ (yr)} \times AF_a \left(\frac{0.07 \text{ mg}}{\text{cm}^2} \right) \times SA_a \left(\frac{5700 \text{ cm}^2}{\text{day}} \right) \times 1}{BW_a \text{ (70 Kg)}}$$

- Total.

$$SL_{res-sol-mu-tot} \text{ (mg/kg)} = \frac{1}{\frac{1}{SL_{res-sol-mu-ing}} + \frac{1}{SL_{res-sol-mu-der}} + \frac{1}{SL_{res-sol-mu-inh}}}$$

4.1.3 Vinyl Chloride - Carcinogenic

The residential soil land use equations, presented here, contain the following exposure routes:

- incidental ingestion of soil,

$$SL_{res-soil-ca-vc-ing} (mg/kg) = \frac{TR}{\left[\frac{CSF_o \left(\frac{mg}{kg \cdot day} \right)^{-1} \times EF_r \left(\frac{350 \text{ days}}{year} \right) \times IF5_{adj} \left(\frac{114 \text{ mg-yr}}{kg \cdot d} \right) \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}{AT \left(\frac{365 \text{ days}}{year} \right) \times LT (70 \text{ years})} \right] + \left[\frac{CSF_o \left(\frac{mg}{kg \cdot day} \right)^{-1} \times IRS_c \left(\frac{200 \text{ mg}}{day} \right) \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}{BW_e (15 \text{ kg})} \right]}$$

- inhalation of particulates emitted from soil,

$$SL_{res-soil-ca-vc-inh} (mg/kg) = \frac{TR}{\left[\frac{IUR \left(\frac{\mu g}{m^3} \right)^{-1} \times EF \left(\frac{350 \text{ days}}{year} \right) \times ED (30 \text{ years}) \times ET_{rs} \left(\frac{24 \text{ hours}}{day} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \left(\frac{1000 \mu g}{mg} \right)}{AT \left(\frac{365 \text{ days}}{year} \right) \times LT (70 \text{ years}) \times VF \left(\frac{m^3}{kg} \right)} \right] + \left[\frac{IUR \left(\frac{\mu g}{m^3} \right)^{-1}}{VF \left(\frac{m^3}{kg} \right)} \times \left(\frac{1000 \mu g}{mg} \right)} \right]}$$

- dermal contact with soil,

$$SL_{res-soil-ca-vc-der} (mg/kg) = \frac{TR}{\left[\frac{CSF_o \left(\frac{mg}{kg \cdot day} \right)^{-1} \times EF_r \left(\frac{350 \text{ days}}{year} \right) \times DF5_{adj} \left(\frac{361 \text{ mg-yr}}{kg \cdot day} \right) \times ABS_d \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}{AT_r \left(\frac{365 \text{ days}}{year} \right) \times LT (70 \text{ years})} \right] + \left[\frac{CSF_o \left(\frac{mg}{kg \cdot day} \right)^{-1}}{GIABS} \times SA_c \left(\frac{2800 \text{ cm}^2}{day} \right) \times AF_c \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times ABS \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}{BW_e (15 \text{ kg})} \right]}$$

- Total.

$$SL_{res-soil-ca-vc-tot} (mg/kg) = \frac{1}{\frac{1}{SL_{res-soil-ca-vc-ing}} + \frac{1}{SL_{res-soil-ca-vc-der}} + \frac{1}{SL_{res-soil-ca-vc-inh}}}$$

A number of studies have shown that inadvertent ingestion of soil is common among children 6 years old and younger (Calabrese et al. 1989, Davis et al. 1990, Van Wijnen et al. 1990). Therefore, the dose method uses an age-adjusted soil ingestion factor that takes into account the difference in daily soil ingestion rates, body weights, and exposure duration for children from 1 to 6 years old and others from 7 to 30 years old. The equation is presented below. This health-protective approach is chosen to take into account the higher daily rates of soil ingestion in children as well as the longer duration of exposure that is anticipated for a long-term resident. For more on this method, see [RAGS Part B](#).

4.2 Composite Worker Soil

This landuse is for developing default screening levels.

4.2.1 Noncancer

The composite worker soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{w-sol-ca-ing} (mg/kg) = \frac{TR \times AT_{ow} \left(\frac{365 \text{ days}}{year} \times LT (70 \text{ years}) \right) \times BW_{ow} (70 \text{ Kg})}{EF_{iw} \left(\frac{250 \text{ days}}{year} \right) \times ED_{ow} (25 \text{ years}) \times CSF_o \left(\frac{mg}{kg \cdot day} \right)^{-1} \times IR_{ow} \left(\frac{100 \text{ mg}}{day} \right) \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- inhalation of particulates emitted from soil,

$$SL_{w-sol-ca-inh} (mg/kg) = \frac{TR \times AT_{ow} \left(\frac{365 \text{ days}}{year} \times LT (70 \text{ years}) \right)}{EF_{iw} \left(\frac{250 \text{ days}}{year} \right) \times ED_{ow} (25 \text{ years}) \times ET_{ws} \left(\frac{8 \text{ hours}}{day} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times IUR \left(\frac{\mu g}{m^3} \right)^{-1} \times \left(\frac{1000 \mu g}{mg} \right) \times \left[\frac{1}{VF_s \left(\frac{m^3}{kg} \right)} + \frac{1}{PEF_w \left(\frac{m^3}{kg} \right)} \right]}$$

- dermal exposure,

$$SL_{w-sol-ca-der} (mg/kg) = \frac{TR \times AT_{ow} \left(\frac{365 \text{ days}}{year} \times LT (70 \text{ years}) \right) \times BW_{ow} (70 \text{ Kg})}{EF_{iw} \left(\frac{250 \text{ days}}{year} \right) \times ED_{ow} (25 \text{ years}) \times \left[\frac{CSF_o \left(\frac{mg}{kg \cdot day} \right)^{-1}}{GIABS} \right] \times SA_{ow} \left(\frac{3300 \text{ cm}^2}{day} \right) \times AF_{ow} \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times ABS_d \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- Total.

$$SL_{w-sol-ca-tot} (mg/kg) = \frac{1}{\frac{1}{SL_{w-sol-ca-ing}} + \frac{1}{SL_{w-sol-ca-der}} + \frac{1}{SL_{w-sol-ca-inh}}}$$

4.2.2 Carcinogenic

The composite worker soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{w-sol-nc-ing} \text{ (mg/kg)} = \frac{THQ \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{ow} \text{ (25 years)} \right) \times BW_{ow} \text{ (70 Kg)}}{EF_{iw} \left(250 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times \frac{1}{RfD_o \left(\frac{\text{mg}}{\text{kg-day}} \right)} \times IR_{ow} \left(\frac{100 \text{ mg}}{\text{day}} \right) \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- inhalation of particulates emitted from soil,

$$SL_{w-sol-nc-inh} \text{ (mg/kg)} = \frac{THQ \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{ow} \text{ (25 years)} \right)}{EF_{iw} \left(250 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times ET_{ws} \left(\frac{8 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \frac{1}{RfC \left(\frac{\text{mg}}{\text{m}^3} \right)} \times \left(\frac{1}{VF_s \left(\frac{\text{m}^3}{\text{kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{kg}} \right)} \right)}$$

- dermal exposure,

$$SL_{w-sol-nc-der} \text{ (mg/kg)} = \frac{THQ \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{ow} \text{ (25 years)} \right) \times BW_{ow} \text{ (70 Kg)}}{EF_{iw} \left(250 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times \frac{1}{RfD_o \left(\frac{\text{mg}}{\text{kg-day}} \right)} \times GI_{ABS} \times SA_{ow} \left(\frac{3300 \text{ cm}^2}{\text{day}} \right) \times AF_{ow} \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times ABS_d \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- Total.

$$SL_{w-sol-nc-tot} \text{ (mg/kg)} = \frac{1}{\frac{1}{SL_{w-sol-nc-ing}} + \frac{1}{SL_{w-sol-nc-der}} + \frac{1}{SL_{w-sol-nc-inh}}}$$

4.3 Indoor Worker Soil

The indoor worker soil land use is not provided in the Generic Tables but SLs can be created by using the Calculator to modify the exposure parameters for the composite worker to match the equations that follow.

4.3.1 Noncancer

The indoor worker soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{iw-nc-ing} \text{ (mg/kg)} = \frac{THQ \times AT_{iw} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{iw} \text{ (25 years)} \right) \times BW_{iw} \text{ (70 Kg)}}{EF_{iw} \left(250 \frac{\text{days}}{\text{year}} \right) \times ED_{iw} \text{ (25 years)} \times \frac{1}{RfD_o \left(\frac{\text{mg}}{\text{kg-day}} \right)} \times IR_{iw} \left(\frac{50 \text{ mg}}{\text{day}} \right) \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- inhalation of particulates emitted from soil,

$$SL_{iw-nc-inh} \text{ (mg/kg)} = \frac{THQ \times AT_{iw} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{iw} \text{ (25 years)} \right)}{EF_{iw} \left(250 \frac{\text{days}}{\text{year}} \right) \times ED_{iw} \text{ (25 years)} \times ET_{ws} \left(\frac{8 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \frac{1}{RfC \left(\frac{\text{mg}}{\text{m}^3} \right)} \times \left(\frac{1}{VF_s \left(\frac{\text{m}^3}{\text{kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{kg}} \right)} \right)}$$

- Total.

$$SL_{iw-nc-tot} \text{ (mg/kg)} = \frac{1}{\frac{1}{SL_{iw-nc-ing}} + \frac{1}{SL_{iw-nc-inh}}}$$

4.3.2 Carcinogenic

The indoor worker soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{iw-ca-ing} \text{ (mg/kg)} = \frac{TR \times AT_{iw} \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right) \times BW_{iw} \text{ (70 Kg)}}{EF_{iw} \left(250 \frac{\text{days}}{\text{year}} \right) \times ED_{iw} \text{ (25 years)} \times CSF_o \left(\frac{\text{mg}}{\text{kg-day}} \right)^{-1} \times IR_{iw} \left(\frac{50 \text{ mg}}{\text{day}} \right) \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- inhalation of particulates emitted from soil,

$$SL_{iw-ca-inh} \text{ (mg/kg)} = \frac{TR \times AT_{iw} \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{EF_{iw} \left(250 \frac{\text{days}}{\text{year}} \right) \times ED_{iw} \text{ (25 years)} \times ET_{ws} \left(\frac{8 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right) \times \left(\frac{1}{VF_s \left(\frac{\text{m}^3}{\text{kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{kg}} \right)} \right)}$$

- Total.

$$SL_{iw-ca-tot} \text{ (mg/kg)} = \frac{1}{\frac{1}{SL_{iw-ca-ing}} + \frac{1}{SL_{iw-ca-inh}}}$$

4.4 Outdoor Worker Soil

The outdoor worker soil land use is not provided in the Generic Tables but SLs can be created by using the Calculator to modify the exposure parameters for the composite worker to match the equations that follow.

4.4.1 Noncancer

The outdoor worker soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{ow-sol-ca-ing} \text{ (mg/kg)} = \frac{TR \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right) \times BW_{ow} \text{ (70 Kg)}}{EF_{ow} \left(225 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times CSF_o \left(\frac{\text{mg}}{\text{kg-day}} \right)^{-1} \times IR_{ow} \left(100 \frac{\text{mg}}{\text{day}} \right) \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- inhalation of particulates emitted from soil,

$$SL_{ow-sol-ca-inh} \text{ (mg/kg)} = \frac{TR \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right)}{EF_{ow} \left(225 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times ET_{ws} \left(\frac{8 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right) \times \left(\frac{1}{VF_s \left(\frac{\text{m}^3}{\text{kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{kg}} \right)} \right)}$$

- dermal exposure,

$$SL_{ow-sol-ca-der} \text{ (mg/kg)} = \frac{TR \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times LT \text{ (70 years)} \right) \times BW_{ow} \text{ (70 Kg)}}{EF_{ow} \left(225 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times \left(\frac{CSF_o \left(\frac{\text{mg}}{\text{kg-day}} \right)^{-1}}{GIABS} \right) \times SA_{ow} \left(\frac{3300 \text{ cm}^2}{\text{day}} \right) \times AF_{ow} \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times ABS_d \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- Total.

$$SL_{ow-sol-ca-tot} \text{ (mg/kg)} = \frac{1}{\frac{1}{SL_{ow-sol-ca-ing}} + \frac{1}{SL_{ow-sol-ca-der}} + \frac{1}{SL_{ow-sol-ca-inh}}}$$

4.4.2 Carcinogenic

The outdoor worker soil land use equation, presented here, contains the following exposure routes:

- incidental ingestion of soil,

$$SL_{ow-sol-nc-ing} \text{ (mg/kg)} = \frac{THQ \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{ow} \text{ (25 years)} \right) \times BW_{ow} \text{ (70 Kg)}}{EF_{ow} \left(225 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times \frac{1}{RfD_o \left(\frac{\text{mg}}{\text{kg-day}} \right)} \times IR_{ow} \left(100 \frac{\text{mg}}{\text{day}} \right) \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- inhalation of particulates emitted from soil,

$$SL_{ow-sol-nc-inh} \text{ (mg/kg)} = \frac{THQ \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{ow} \text{ (25 years)} \right)}{EF_{ow} \left(225 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times ET_{ws} \left(\frac{8 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \frac{1}{RfC \left(\frac{\text{mg}}{\text{m}^3} \right)} \times \left(\frac{1}{VF_s \left(\frac{\text{m}^3}{\text{kg}} \right)} + \frac{1}{PEF_w \left(\frac{\text{m}^3}{\text{kg}} \right)} \right)}$$

- dermal exposure,

$$SL_{ow-sol-nc-der} \text{ (mg/kg)} = \frac{THQ \times AT_{ow} \left(\frac{365 \text{ days}}{\text{year}} \times ED_{ow} \text{ (25 years)} \right) \times BW_{ow} \text{ (70 Kg)}}{EF_{ow} \left(225 \frac{\text{days}}{\text{year}} \right) \times ED_{ow} \text{ (25 years)} \times \left(\frac{1}{RfD_o \left(\frac{\text{mg}}{\text{kg-day}} \right) \times GIABS} \right) \times SA_{ow} \left(\frac{3300 \text{ cm}^2}{\text{day}} \right) \times AF_{ow} \left(\frac{0.2 \text{ mg}}{\text{cm}^2} \right) \times ABS_d \times \left(\frac{10^{-6} \text{ Kg}}{1 \text{ mg}} \right)}$$

- Total.

$$SL_{\text{ow-sol-nc-tot}} (\text{mg/kg}) = \frac{1}{\frac{1}{SL_{\text{ow-sol-nc-ing}}} + \frac{1}{SL_{\text{ow-sol-nc-der}}} + \frac{1}{SL_{\text{ow-sol-nc-inh}}}}$$

4.5 Tapwater

The Tapwater calculations do not include the dermal exposure route. It was determined that too many analytes were outside of the EPA Superfund Dermal Risk Assessment Guidance (RAGS Part E)'s Effective Predictive Domain (EPD) to include a dermal permeability constant (K_p). Some of these were significant analytes, such as persistent chlorinated organics, including PCBs. K_p can be determined from the molecular weight and the logKow for organic compounds. Compounds with very high log Kows are outside of the EPD. Section 3.1.2 of [RAGS Part E](#) provides more detail.

4.5.1 Noncarcinogenic

The tapwater land use equation, presented here, contains the following exposure routes:

- ingestion of water,

$$SL_{\text{water-nc-ing}} (\mu\text{g/L}) = \frac{\text{THQ} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{ED}_r (30 \text{ years}) \right) \times \text{BW}_a (70 \text{ Kg}) \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right)}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{ED}_r (30 \text{ years}) \times \frac{1}{\text{RfD}_o \left(\frac{\text{mg}}{\text{kg-d}} \right)} \times \text{IRW}_a \left(\frac{2 \text{ L}}{\text{day}} \right)}$$

- inhalation of volatiles,

$$SL_{\text{water-nc-inh}} (\mu\text{g/L}) = \frac{\text{THQ} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{ED}_r (30 \text{ years}) \right) \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right)}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{ED}_r (30 \text{ years}) \times \text{ET}_{\text{rw}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \frac{1}{\text{RFC} \left(\frac{\text{mg}}{\text{m}^3} \right)} \times \text{K} \left(\frac{0.5 \text{ L}}{\text{m}^3} \right)}$$

- Total.

$$SL_{\text{water-nc-tot}} (\mu\text{g/L}) = \frac{1}{\frac{1}{SL_{\text{water-nc-ing}}} + \frac{1}{SL_{\text{water-nc-inh}}}}$$

4.5.2 Carcinogenic

The tapwater land use equation, presented here, contains the following exposure routes:

- ingestion of water,

$$SL_{\text{water-ca-ing}} (\mu\text{g/L}) = \frac{\text{TR} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{LT} (70 \text{ years}) \right) \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right)}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{CSF}_o \left(\frac{\text{mg}}{\text{kg-day}} \right)^{-1} \times \left(\text{IFW}_{\text{adj}} \left(\frac{1.086 \text{ L-Year}}{\text{Kg-day}} \right) \right)}$$

where:

$$\text{IFW}_{\text{adj}} \left(\frac{1.086 \text{ L-Year}}{\text{Kg-day}} \right) = \frac{\text{ED}_c (6 \text{ years}) \times \text{IRW}_c \left(\frac{1 \text{ L}}{\text{day}} \right)}{\text{BW}_c (15 \text{ Kg})} + \frac{\text{ED}_r - \text{ED}_c (24 \text{ years}) \times \text{IRW}_a \left(\frac{2 \text{ L}}{\text{day}} \right)}{\text{BW}_a (70 \text{ Kg})}$$

- inhalation of volatiles,

$$SL_{\text{water-ca-inh}} (\mu\text{g/L}) = \frac{\text{TR} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{LT} (70 \text{ years}) \right)}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{ED}_r (30 \text{ years}) \times \text{ET}_{\text{rw}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \text{IUR} \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times \text{K} \left(\frac{0.5 \text{ L}}{\text{m}^3} \right)}$$

- Total.

$$SL_{\text{water-ca-tot}} (\mu\text{g/L}) = \frac{1}{\frac{1}{SL_{\text{water-ca-ing}}} + \frac{1}{SL_{\text{water-ca-inh}}}}$$

4.5.3 Mutagenic

The tapwater land use equation, presented here, contains the following exposure routes:

- ingestion of water,

$$SL_{\text{water-mu-ing}} (\mu\text{g/L}) = \frac{\text{TR} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{LT} (70 \text{ years}) \right) \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right)}{\text{CSF}_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)^{-1} \times \text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{IFWM}_{\text{adj}} \left(\frac{3.39 \text{ L-Year}}{\text{Kg-day}} \right)}$$

where:

$$\text{IFWM}_{\text{adj}} \left(\frac{3.39 \text{ L-Year}}{\text{Kg-day}} \right) = \frac{\text{ED}_{0-2} (\text{yr}) \times \text{IRW}_c \left(\frac{1 \text{ L}}{\text{day}} \right) \times 10}{\text{BW}_c (15 \text{ Kg})} + \frac{\text{ED}_{2-6} (\text{yr}) \times \text{IRW}_c \left(\frac{1 \text{ L}}{\text{day}} \right) \times 3}{\text{BW}_c (15 \text{ Kg})} + \frac{\text{ED}_{6-16} (\text{yr}) \times \text{IRW}_a \left(\frac{2 \text{ L}}{\text{day}} \right) \times 3}{\text{BW}_a (70 \text{ Kg})} + \frac{\text{ED}_{16-30} (\text{yr}) \times \text{IRW}_a \left(\frac{2 \text{ L}}{\text{day}} \right) \times 1}{\text{BW}_a (70 \text{ Kg})}$$

- inhalation of volatiles,

$$SL_{\text{water-mu-inh}} (\mu\text{g/L}) = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT (70 \text{ years}) \right)}{EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times K \left(\frac{0.5 \text{ L}}{\text{m}^3} \right) \times ET_{\text{rw}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \left(\left(ED_{0-2} (\text{yrs}) \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 10 \right) + \left(ED_{2-6} (\text{yrs}) \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 3 \right) + \left(ED_{6-16} (\text{yrs}) \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 3 \right) + \left(ED_{16-30} (\text{yrs}) \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times 1 \right) \right)}$$

- Total.

$$SL_{\text{water-mu-tot}} (\mu\text{g/L}) = \frac{1}{\frac{1}{SL_{\text{water-mu-ing}}} + \frac{1}{SL_{\text{water-mu-inh}}}}$$

4.5.4 Vinyl Chloride - Carcinogenic

The tapwater land use equation, presented here, contains the following exposure routes:

- ingestion of water,

$$SL_{\text{res-water-ca-vc-ing}} (\mu\text{g/L}) = \frac{TR}{\left(\frac{CSF_o \left(\frac{\text{mg}}{\text{kg-day}} \right)^{-1} \times EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times IFW_{\text{adj}} \left(\frac{1.086 \text{ L-yr}}{\text{kg-day}} \right) \times \left(\frac{\text{mg}}{1000 \mu\text{g}} \right)}{AT \left(\frac{365 \text{ days}}{\text{year}} \right) \times LT (70 \text{ years})} \right) + \left(\frac{CSF_o \left(\frac{\text{mg}}{\text{kg-day}} \right)^{-1} \times IRW_c \left(\frac{1 \text{ L}}{\text{day}} \right) \times \left(\frac{\text{mg}}{1000 \mu\text{g}} \right)}{BW_c (15 \text{ kg})} \right)}$$

- inhalation of volatiles,

$$SL_{\text{res-water-ca-vc-inh}} (\mu\text{g/L}) = \frac{TR}{\left(\frac{IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times ED (30 \text{ years}) \times ET_{\text{rw}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times K \left(\frac{0.5 \text{ L}}{\text{m}^3} \right)}{AT \left(\frac{365 \text{ days}}{\text{year}} \right) \times LT (70 \text{ years})} \right) + \left(IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1} \times K \left(\frac{0.5 \text{ L}}{\text{m}^3} \right) \right)}$$

- Total.

$$SL_{\text{res-water-ca-vc-tot}} (\mu\text{g/L}) = \frac{1}{\frac{1}{SL_{\text{res-water-ca-vc-ing}}} + \frac{1}{SL_{\text{res-water-ca-vc-inh}}}}$$

4.6 Resident Ambient Air

4.6.1 Noncarcinogenic

The Ambient air land use equation, presented here, contains the following exposure routes:

- inhalation of volatiles

$$SL_{\text{res-air-nc}} (\mu\text{g}/\text{m}^3) = \frac{THQ \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times ED_r (30 \text{ years}) \right) \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right)}{EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times ED_r (30 \text{ years}) \times ET_{\text{ra}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \frac{1}{RFC \left(\frac{\text{mg}}{\text{m}^3} \right)}}$$

4.6.2 Carcinogenic

The Ambient air land use equation, presented here, contains the following exposure routes:

- inhalation of volatiles

$$SL_{\text{res-air-ca}} (\mu\text{g}/\text{m}^3) = \frac{TR \times AT_r \left(\frac{365 \text{ days}}{\text{year}} \times LT (70 \text{ years}) \right)}{EF_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times ED_r (30 \text{ years}) \times ET_{\text{ra}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times IUR \left(\frac{\mu\text{g}}{\text{m}^3} \right)^{-1}}$$

4.6.3 Vinyl Chloride - Carcinogenic

The Ambient air land use equation, presented here, contains the following exposure routes:

- inhalation of volatiles

$$SL_{\text{res-air-ca-vinyl chloride}} (\mu\text{g}/\text{m}^3) = \frac{\text{TR}}{\text{IUR} (\mu\text{g}/\text{m}^3)^{-1} + \left(\frac{\text{TR} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{LT} (70 \text{ years}) \right)}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{ET}_{\text{ra}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right)} \right)}$$

4.6.4 Mutagenic

The Ambient air land use equation, presented here, contains the following exposure routes:

- inhalation of volatiles

$$SL_{\text{res-air-mu}} (\mu\text{g}/\text{m}^3) = \frac{\text{TR} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{LT} (70 \text{ years}) \right)}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{ET}_{\text{ra}} \left(\frac{24 \text{ hours}}{\text{day}} \right) \times \left(\frac{1 \text{ day}}{24 \text{ hours}} \right) \times \left(\text{ED}_{0-2} (\text{yrs}) \times \text{IUR} (\mu\text{g}/\text{m}^3)^{-1} \times 10 + \left(\text{ED}_{2-6} (\text{yrs}) \times \text{IUR} (\mu\text{g}/\text{m}^3)^{-1} \times 3 \right) + \left(\text{ED}_{6-16} (\text{yrs}) \times \text{IUR} (\mu\text{g}/\text{m}^3)^{-1} \times 3 \right) + \left(\text{ED}_{16-30} (\text{yrs}) \times \text{IUR} (\mu\text{g}/\text{m}^3)^{-1} \times 1 \right) \right)}$$

4.7 Worker Ambient Air

4.7.1 Noncarcinogenic

The Ambient air land use equation, presented here, contains the following exposure routes:

- Inhalation of volatiles

$$SL_{\text{w-air-nc}} (\mu\text{g}/\text{m}^3) = \frac{\text{THQ} \times \text{AT}_w \left(\frac{365 \text{ days}}{\text{year}} \times \text{ED}_r (25 \text{ years}) \right) \times \left(\frac{1000 \mu\text{g}}{\text{mg}} \right)}{\text{EF}_w \left(\frac{250 \text{ days}}{\text{year}} \right) \times \text{ED}_w (25 \text{ years}) \times \text{ET}_w \left(\frac{8 \text{ hr}}{24 \text{ hr}} \right) \times \frac{1}{\text{Rfc} (\text{mg}/\text{m}^3)}}$$

4.7.2 Carcinogenic

The Ambient air land use equation, presented here, contains the following exposure routes:

- Inhalation of volatiles

$$SL_{\text{w-air-ca}} (\mu\text{g}/\text{m}^3) = \frac{\text{TR} \times \text{AT}_w \left(\frac{365 \text{ days}}{\text{year}} \times \text{LT} (70 \text{ years}) \right)}{\text{EF}_w \left(\frac{250 \text{ days}}{\text{year}} \right) \times \text{ED}_w (25 \text{ years}) \times \text{ET}_w \left(\frac{8 \text{ hr}}{24 \text{ hr}} \right) \times \text{IUR} (\mu\text{g}/\text{m}^3)^{-1}}$$

4.8 Ingestion of Fish

The ingestion of fish exposure route is not provided in the Generic Tables but SLs can be created by using the Calculator and the equations that follow:

4.8.1 Noncarcinogenic

The ingestion of fish equation, presented here, contains the following exposure route:

- consumption of fish.

$$SL_{\text{res-fsh-nc-ing}} (\text{mg}/\text{kg}) = \frac{\text{THQ} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{ED}_c (30 \text{ years}) \right) \times \text{BW}_a (70 \text{ Kg})}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{ED}_c (30 \text{ year}) \times \frac{1}{\text{RFD}_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)} \times \text{IRF}_a \left(\frac{5.4 \times 10^4 \text{ mg}}{\text{day}} \right) \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}$$

4.8.2 Carcinogenic

The ingestion of fish equation, presented here, contains the following exposure route:

- consumption of fish.

$$SL_{\text{res-fsh-ca-ing}} (\text{mg}/\text{kg}) = \frac{\text{TR} \times \text{AT}_r \left(\frac{365 \text{ days}}{\text{year}} \times \text{LT} (70 \text{ years}) \right) \times \text{BW}_a (70 \text{ Kg})}{\text{EF}_r \left(\frac{350 \text{ days}}{\text{year}} \right) \times \text{ED}_c (30 \text{ year}) \times \text{CSF}_o \left(\frac{\text{mg}}{\text{Kg-day}} \right)^{-1} \times \text{IRF}_a \left(\frac{5.4 \times 10^4 \text{ mg}}{\text{day}} \right) \times \frac{10^{-6} \text{ Kg}}{1 \text{ mg}}}$$

Note: the consumption rate for fish is not age adjusted for this land use. Also the SL calculated for fish is not for soil, like for the agricultural land uses, but is for fish tissue.

4.9 Soil to Groundwater

These equations are used to calculate screening levels in soil (SSLs) that are protective of groundwater. SSLs are either back-calculated from protective risk-based ground water concentrations or based on MCLs. The SSLs were designed for use during the early stages of a site evaluation when information about subsurface conditions may be limited. Because of this constraint, the equations used are based on conservative, simplifying assumptions about the release and transport of contaminants in the subsurface. Migration of contaminants from soil to groundwater can be envisioned as a two-stage process: (1) release of contaminant in soil leachate and (2) transport of the contaminant through the underlying soil and aquifer to a receptor well. The SSL methodology considers both of these fate and transport mechanisms.

SSLs are provided for metals in the Generic Tables based on Kds from the [Soil Screening Guidance Exhibit C-4](#). According to Appendix C,

"Exhibit C-4 provides pH-specific soil-water partition coefficients (Kd) for metals. Site-specific soil pH measurements can be used to select appropriate Kd values for these metals. Where site-specific soil pH values are not available, values corresponding to a pH of 6.8 should be used."

Because Kds vary greatly by soil type, it is highly recommended that site-specific Kds be determined and used to develop SSLs.

The more protective of the carcinogenic and noncarcinogenic SLs is selected to calculate the SSL.

4.9.1 Noncarcinogenic Tapwater Equations for SSLs

The tapwater equations, presented in Section 4.4.1, are used to calculate the noncarcinogenic SSLs for volatiles and nonvolatiles. If the contaminant is a volatile, both ingestion and inhalation exposure routes are considered. If the contaminant is not a volatile, only ingestion is considered.

4.9.2 Carcinogenic Tapwater Equations for SSLs

The tapwater equations, presented in Section 4.4.2, are used to calculate the carcinogenic SSLs for volatiles and nonvolatiles. Sections 4.4.3 and 4.4.4 present the mutagenic and vinyl chloride equations, respectively. If the contaminant is a volatile, both ingestion and inhalation exposure routes are considered. If the contaminant is not a volatile, only ingestion is considered.

4.9.3 Method 1 for SSL Determination

Method 1 employs a partitioning equation for migration to groundwater and defaults are provided. This method is used to generate the download default tables.

- method 1.

$$SSL \left(\frac{mg}{kg} \right) = C_w \left(\frac{mg}{L} \right) \times \left[K_d \left(\frac{L}{kg} \right) + \frac{\left(\theta_w \left(\frac{L_{water}}{L_{soil}} \right) + \theta_a \left(\frac{L_{air}}{L_{soil}} \right) \times H' \right)}{\rho_b \left(\frac{1.5 \text{ kg}}{L} \right)} \right]$$

where:

$$\theta_a \left(\frac{L_{air}}{L_{soil}} \right) = n \left(\frac{L_{water}}{L_{soil}} \right) - \theta_w \left(\frac{0.3 L_{water}}{L_{soil}} \right);$$

$$n \left(\frac{L_{pore}}{L_{soil}} \right) = 1 - \left(\frac{\rho_b \left(\frac{1.5 \text{ kg}}{L} \right)}{\rho_s \left(\frac{2.65 \text{ kg}}{L} \right)} \right) \text{ and}$$

$$K_d \left(\frac{L}{kg} \right) = K_{oc} \left(\frac{L}{kg} \right) \times f_{oc} \text{ (0.002 unitless)}$$

4.9.4 Method 2 for SSL Determination

Method 2 employs a mass-limit equation for migration to groundwater and site-specific information is required. This method can be used in the calculator portion of this website.

- method 2.

$$SSL \left(\frac{mg}{kg} \right) = \frac{C_w \left(\frac{mg}{L} \right) \times I \left(\frac{0.18 \text{ m}}{\text{year}} \right) \times ED \text{ (70 years)}}{\rho_b \left(\frac{1.5 \text{ kg}}{L} \right) \times d_s \text{ (m)}}$$

4.9.5 Determination of the Dilution Factor

The SSL values in the download tables are based on a dilution factor of 1. The dilution factor default for the calculator is 20 for 0.5 acre source. If all of the parameters needed to calculate a site-specific dilution factor are known, they may be entered.

- dilution factor.

$$\text{Dilution Attenuation Factor} = 1 + \frac{K \left(\frac{m}{\text{year}} \right) \times i \left(\frac{m}{m} \right) \times d \text{ (m)}}{I \left(\frac{0.18 \text{ m}}{\text{year}} \right) \times L \text{ (m)}}$$

where:

$$d \text{ (m)} = \left(0.0112 \times L^2 \text{ (m)} \right)^{0.5} + d_a \times \left[1 - \exp \left(\frac{-L \text{ (m)} \times I \left(\frac{m}{\text{year}} \right)}{K \left(\frac{m}{\text{year}} \right) \times i \left(\frac{m}{m} \right) \times d_a \text{ (m)}} \right) \right]$$

4.10 Supporting Equations and Parameter Discussion

There are two parts of the above land use equations that require further explanation. They are the inhalation variables: the particulate emission factor (PEF) and the volatilization factor (VF).

4.10.1 Particulate Emission Factor (PEF)

Inhalation of contaminants adsorbed to respirable particles (PM10) was assessed using a default PEF equal to 1.36×10^9 m³/kg. This equation relates the contaminant concentration in soil with the concentration of respirable particles in the air due to fugitive dust emissions from contaminated soils. The generic PEF was derived using default values that correspond to a receptor point concentration of approximately 0.76 ug/m³. The relationship is derived by Cowherd (1985) for a rapid assessment procedure applicable to a typical hazardous waste site, where the surface contamination provides a relatively continuous and constant potential for emission over an extended period of time (e.g., years). This represents an annual average emission rate based on wind erosion that should be compared with chronic health criteria; it is not appropriate for evaluating the potential for more acute exposures. Definitions of the input variables are in [Table 1](#).

With the exception of specific heavy metals, the PEF does not appear to significantly affect most soil screening levels. The equation forms the basis for deriving a generic PEF for the inhalation pathway. For more details regarding specific parameters used in the PEF model, refer to [Soil Screening Guidance: Technical Background Document](#). The use of alternate values on a specific site should be justified and presented in an Administrative Record if considered in CERCLA remedy selection.

$$PEF_w = \frac{Q}{C_w} \times \frac{3,600}{0.036 \times (1-V) \times (U_m/U_t)^3 \times F(x)}$$

where

$$\frac{Q}{C_w} = A \times \exp\left[\frac{(\ln A_s - B)^2}{C}\right]$$

Note: the generic PEF evaluates wind-borne emissions and does not consider dust emissions from traffic or other forms of mechanical disturbance that could lead to greater emissions than assumed here.

4.10.2 Volatilization Factor (VF)

The soil-to-air VF is used to define the relationship between the concentration of the contaminant in soil and the flux of the volatilized contaminant to air. VF is calculated from the equation below using chemical-specific properties and either site-measured or default values for soil moisture, dry bulk density, and fraction of organic carbon in soil. The [Soil Screening Guidance: User's Guide](#) describes how to develop site measured values for these parameters.

VF is only calculated for volatile organic compounds (VOCs). VOCs, for the purpose of this guidance, are chemicals with a Henry's Law constant of 1×10^{-5} atm-m³/mole or greater and with a molecular weight of less than 200 g/mole.

$$VF = \frac{\frac{Q}{C_w} \times (3.14 \times D_A \times T)^{\frac{1}{2}} \times 10^{-4} \left(\frac{m^2}{cm^2}\right)}{2 \times \rho_b \times D_A}$$

where

$$\frac{Q}{C_w} = A \times \exp\left[\frac{(\ln A_s - B)^2}{C}\right] \text{ and}$$

$$D_A = \frac{\left[\left(\theta_a^{\frac{10}{3}} \times D_{ia} \times H' + \theta_w^{\frac{10}{3}} \times D_{iw}\right) / n^2\right]}{\rho_b \times K_d + \theta_w + \theta_a \times H'}$$

Diffusivity in Water (cm²/s)

Diffusivity in water can be calculated from the chemical's molecular weight and density, using the following correlation equation based on WATER9 ([U.S. EPA, 2001](#)):

$$D_{iw} \left(\frac{cm^2}{s}\right) = 0.0001518 \times \left(\frac{T^{\circ}C + 273.16}{298.16}\right) \times \left(\frac{MW \left(\frac{g}{mol}\right)}{\rho \left(\frac{g}{cm^3}\right)}\right)^{-0.6}$$

where

T typically = 25°C

If density is not available,

$$D_{iw} \left(\frac{cm^2}{s}\right) = 0.000222 \times (MW)^{-\left(\frac{2}{3}\right)}$$

If density is not available, diffusivity in water can be calculated using the correlation equation based on U.S. EPA (1987). The value for diffusivity in water must be greater than zero. No maximum limit is enforced.

Diffusivity in Air (cm²/s).

Diffusivity in air can be calculated from the chemical's molecular weight and density, using the following correlation equation based on WATER9 (U.S. EPA, 2001):

$$D_{ia} \left(\frac{\text{cm}^2}{\text{s}} \right) = \frac{0.00229 \times (T^{\circ}\text{C} + 273.16)^{1.5} \times \left[0.034 + \left(\frac{1}{\text{MW} \left(\frac{\text{g}}{\text{mol}} \right)} \right) \times \text{MW}_{\text{cor}} \right]}{\left(\left(\frac{\text{MW} \left(\frac{\text{g}}{\text{mol}} \right)}{2.5 \times \rho \left(\frac{\text{g}}{\text{cm}^3} \right)} \right)^{0.333} + 1.8 \right)^2}$$

where

T typically = 25 °C

$\text{MW}_{\text{cor}} = (1 - 0.000015 \times \text{MW}^2)$ If MW_{cor} is less than 0.4, then MW_{cor} is set to 0.4.

If density is not available,

$$D_{ia} \left(\frac{\text{cm}^2}{\text{s}} \right) = 1.9 \times \left(\text{MW} \left(\frac{\text{g}}{\text{mol}} \right) \right)^{-\left(\frac{2}{3} \right)} \text{ except for dioxins use, } D_{ia} \left(\frac{\text{cm}^2}{\text{s}} \right) = \left(\frac{154}{\text{MW} \left(\frac{\text{g}}{\text{mol}} \right)} \right)^{0.5} \times 0.068$$

If density is not available, diffusivity in air can be calculated using the correlation equation based on U.S. EPA (1987). For dioxins, diffusivity in air can be calculated from the molecular weight using the correlation equation based on EPA's Dioxin Reassessment (U.S. EPA, 2000).

5. Special Considerations

Most of the SLs are readily derived by referring to the above equations. However, there are some cases for which the standard equations do not apply and/or external adjustments to the SLs are recommended. These special case chemicals are discussed below.

5.1 Cadmium

IRIS presents an oral "water" RfD for cadmium for use in assessment of risks to water of 0.0005 mg/kg-day. IRIS also presents an oral "food" RfD for cadmium for use in assessment of risks to soil and biota of 0.001 mg/kg-day. The SLs for Cadmium are based on the oral RfD for "water", which is slightly more conservative (by a factor of 2) than the RfD for "food". Because the SLs are considered screening values, the more conservative RfD is used for cadmium. However, reasonable arguments could be made for applying an RfD for food (instead of the oral RfD for water) for some media such as soils. RAGS Part E, in Exhibit 4-1, presents a GIABS for soil of 2.5% and for water of 5%.

5.2 Lead

EPA has no consensus RfD or CSF for inorganic lead, so it is not possible to calculate SLs as we have done for other chemicals. EPA considers lead to be a special case because of the difficulty in identifying the classic "threshold" needed to develop an RfD.

EPA therefore evaluates lead exposure by using blood-lead modeling, such as the Integrated Exposure-Uptake Biokinetic Model (IEUBK). The EPA Office of Solid Waste has also released a detailed directive on risk assessment and cleanup of residential soil lead. The directive recommends that soil lead levels less than 400 mg/kg are generally safe for residential use. Above that level, the document suggests collecting data and modeling blood-lead levels with the IEUBK model. For the purposes of screening, therefore, 400 mg/kg is recommended for residential soils. For water, we suggest 15 ug/l (the EPA Action Level in water), and for air, the National Ambient Air Quality Standard.

However, caution should be used when both water and soil are being assessed. The IEUBK model shows that if the average soil concentration is 400 mg/kg, an average tap water concentration above 5 ug/L would yield more than 5% of the population above a 10 ug/dL blood-lead level. If the average tap water concentration is 15 ug/L, an average soil concentration greater than 250 mg/kg would yield more than 5% of the population above a 10 ug/dL blood-lead level.

EPA uses a second Adult Lead Model to estimate SLs for an industrial setting. This SL is intended to protect a fetus that may be carried by a pregnant female worker. It is assumed that a cleanup goal that is protective of a fetus will also afford protection for male or female adult workers. The model equations were developed to calculate cleanup goals such that the fetus of a pregnant female worker would not likely have an unsafe concentration of lead in blood.

For more information on EPA's lead models and other lead-related topics, please go to [Addressing Lead at Superfund Sites](#).

5.3 Manganese

The IRIS RfD (0.14 mg/kg-day) includes manganese from all sources, including diet. The author of the IRIS assessment for manganese recommended that the dietary contribution from the normal U.S. diet (an upper limit of 5 mg/day) be subtracted when evaluating non-food (e.g., drinking water or soil) exposures to manganese, leading to a RfD of 0.071 mg/kg-day for non-food items. The explanatory text in IRIS further recommends using a modifying factor of 3 when calculating risks associated with non-food sources due to a number of uncertainties that are discussed in the IRIS file for manganese, leading to a RfD of 0.024 mg/kg-day. This modified RfD has been used in the derivation of some manganese screening levels for soil and water. For more information regarding the Manganese RfD, users are advised to contact the author of the IRIS assessment on Manganese.

5.4 Vanadium and Thallium Compounds

The oral RfD for Thallium, used in this website, is derived from the IRIS oral RfD for Thallium Sulfate by factoring out the molecular weight (MW) of the sulfate ion. Thallium Sulfate (Tl_2SO_4) has a molecular weight of 504.82. The two atoms of Thallium contribute 81% of the MW. Thallium Sulfate's oral RfD of 8E-05 multiplied by 81% gives a Thallium oral RfD of 6.48E-05.

The oral RfD toxicity value for Vanadium, used in this website, is derived from the IRIS oral RfD for Vanadium Pentoxide by factoring out the molecular weight (MW) of the oxide ion. Vanadium Pentoxide (V_2O_5) has a molecular weight of 181.88. The two atoms of Vanadium contribute 56% of the MW. Vanadium Pentoxide's oral RfD of 9E-03 multiplied by 56% gives a Vanadium oral RfD of 5.04E-03.

5.5 Uranium

"Uranium Soluble Salts" uses the IRIS oral RfD of 3E-03. For the insoluble salts of Uranium, the oral RfD of 6E-04 may be used from the Federal Register, Thursday December 7, 2000. Part II, Environmental Protection Agency. 40 CFR Parts 9, 141, and 142 - National Primary Drinking Water Regulations; Radionuclides; Final Rule. p 76713.

5.6 Chromium (VI)

For Chromium (VI) (Cr6), IRIS shows an air unit risk of 1.2E-2 per (ug/m³). However, the supporting documentation in the IRIS file states that this toxicity value is based on an assumed 1:6 ratio of Cr6:Cr3. Because of this assumption and in an effort to be transparent, RSLs based on this cancer toxicity value are presented as "Chromium, Total (1:6 ratio Cr VI:III)" numbers.

In the RSL Table, the Cr6 specific value (assuming 100% Cr6) is derived by multiplying the IRIS Cr6 value by 7. This is considered to be a conservative and protective and is consistent with the State of California's interpretation of the Mancuso study that forms the basis of Cr6's toxicity values.

It is recommended that valent-specific data for Chromium be collected when Chromium is likely to be an important contaminant at a site, and when Cr6 may exist. In the absence of valent-specific data, screening levels for total Chromium are provided. If you are working on a chromium site, you may want to contact the appropriate regulatory officials in your region to determine what their position is on this issue.

5.7 Aminodinitrotoluenes

The IRIS oral RfD of 2E-03 for 2,4-Dinitrotoluene is used as a surrogate for 2-Amino-4,6-Dinitrotoluene and 4-Amino-2,6-Dinitrotoluene.

5.8 PCBs

Aroclor 1016 is considered low risk and assigned appropriate toxicity values. All other Aroclors are assigned the high risk toxicity values.

5.9 Soil Saturation Limit (C_{sat})

The soil saturation concentration, C_{sat} , corresponds to the contaminant concentration in soil at which the absorptive limits of the soil particles, the solubility limits of the soil pore water, and saturation of soil pore air have been reached. Above this concentration, the soil contaminant may be present in free phase (i.e., nonaqueous phase liquids (NAPLs) for contaminants that are liquid at ambient soil temperatures and pure solid phases for compounds that are solid at ambient soil temperatures).

Equation 4-10 is used to calculate C_{sat} for each volatile contaminant. As an update to RAGS HHEM, Part B (USEPA 1991a), this equation takes into account the amount of contaminant that is in the vapor phase in soil in addition to the amount dissolved in the soil's pore water and sorbed to soil particles.

Chemical-specific C_{sat} concentrations must be compared with each VF-based SL because a basic principle of the SL volatilization model is not applicable when free-phase contaminants are present. How these cases are handled depends on whether the contaminant is liquid or solid at ambient temperatures. Liquid contaminant that have a VF-based SL that exceeds the C_{sat} concentration are set equal to C_{sat} whereas for solids (e.g., PAHs), soil screening decisions are based on the appropriate SLs for other pathways of concern at the site (e.g., ingestion).

$$C_{sat} = \frac{s \left(\frac{mg}{L} \right)}{\rho_b \left(\frac{Kg}{L} \right)} \times \left(K_d \left(\frac{L}{Kg} \right) \times \rho_b \left(\frac{Kg}{L} \right) + \theta_w \left(\frac{L_{water}}{L_{soil}} \right) + H' \times \theta_a \left(\frac{L_{air}}{L_{soil}} \right) \right)$$

where

$$K_d = K_{oc} \left(\frac{L}{Kg} \right) \times f_{oc} \left(\frac{g}{g} \right),$$

$$\theta_a \left(\frac{L_{air}}{L_{soil}} \right) = n \left(\frac{L_{pore}}{L_{soil}} \right) - \theta_w \left(\frac{L_{water}}{L_{soil}} \right) \text{ and}$$

$$n = 1 - \left(\frac{\rho_b \left(\frac{Kg}{L} \right)}{\rho_s \left(\frac{Kg}{L} \right)} \right)$$

5.10 SL Theoretical Ceiling Limit

The ceiling limit of 10⁺⁵ mg/kg is equivalent to a chemical representing 10% by weight of the soil sample. At this contaminant concentration (and higher), the assumptions for soil contact may be violated (for example, soil adherence and wind-borne dispersion assumptions) due to the presence of the foreign substance itself.

5.11 Target Risk

With the exceptions described previously in Sections 5.6 and 5.7, SLs are chemical concentrations that correspond to fixed levels of risk (i.e., either a one-in-one million [10⁻⁶] cancer risk or a noncarcinogenic hazard quotient of 1) in soil, air, and water. In most cases, where a substance causes both cancer and noncancer (systemic) effects, the 10⁻⁶ cancer risk will result in a more stringent criteria and consequently this value is presented in the printed copy of the

Table. SL concentrations that equate to a 10^{-6} cancer risk are indicated by 'ca'. SL concentrations that equate to a hazard quotient of 1 for noncarcinogenic concerns are indicated by 'nc'.

If the SLs are to be used for site screening, it is recommended that both cancer and noncancer-based SLs be used. Both carcinogenic and noncarcinogenic values may be obtained in the Supporting Tables.

Some users of this SL Table may plan to multiply the cancer SL concentrations by 10 or 100 to set 'action levels' for triggering remediation or to set less stringent cleanup levels for a specific site after considering non-risk-based factors such as ambient levels, detection limits, or technological feasibility. This risk management practice recognizes that there may be a range of values that may be 'acceptable' for carcinogenic risk (EPA's risk management range is one-in-a-million [10^{-6}] to one-in-ten thousand [10^{-4}]). However, this practice could lead one to overlook serious noncancer health threats and it is strongly recommended that the user consult with a toxicologist or regional risk assessor before doing this. Carcinogens are indicated by an asterisk (*) in the SL Table where the noncancer SLs would be exceeded if the cancer value that is displayed is multiplied by 100. (***) indicate that the noncancer values would be exceeded if the cancer SL were multiplied by 10. There is no range of 'acceptable' noncarcinogenic 'risk' for CERCLA sites. Therefore, the noncancer SLs should not be multiplied by 10 or 100 when setting final cleanup criteria. In the rare case where noncancer SLs are more stringent than cancer SLs set at one-in-one-million risk, a similar approach has been applied (e.g. 'max').

SL concentrations in the printed Table are risk-based, but for soil there are two important exceptions: (1) for several volatile chemicals, SLs may exceed the soil saturation level ('sat') and (2) SLs may exceed a non-risk based 'ceiling limit' concentration of 10^{+5} mg/kg ('max') for relatively less toxic inorganic and semivolatile contaminants. For more information on the 'sat' value in the SL Table, please see the discussion in Section 5.8. For more information on the 'max' value in the SL Table, please see the discussion in Section 5.9.

With respect to applying a 'ceiling limit' for chemicals other than volatiles, it is recognized that this is not a universally accepted approach. Some within the agency argue that all values should be risk-based to allow for scaling (for example, if the risk-based SL is set at a hazard quotient = 1.0, and the user would like to set the hazard quotient to 0.1 to take into account multiple chemicals, then this is as simple as multiplying the risk-based SL by 1/10th). If scaling is necessary, SL users can do this simply by referring to the Supporting Tables at this website where risk-based soil concentrations are presented for all chemicals.

In spite of the fact that applying a ceiling limit is not a universally accepted approach, this table applies a 'max' soil concentration to the SL Table for the following reasons:

- Risk-based SLs for some chemicals in soil exceed unity ($>1,000,000$ mg/kg), which is not possible.
- The ceiling limit of 10^{+5} mg/kg is equivalent to a chemical representing 10% by weight of the soil sample. At this contaminant concentration (and higher), the assumptions for soil contact may be violated (for example, soil adherence and wind-borne dispersion assumptions) due to the presence of the foreign substance itself.
- SLs currently do not address short-term exposures (e.g., pica children and construction workers). Although extremely high soil SLs are likely to represent relatively non-toxic chemicals, such high values may not be justified if in fact more toxicological data were available for evaluating short-term and/or acute exposures.

5.12 Screening Sites with Multiple Contaminants

Since the screening levels in the tables are contaminant specific, users needing to screen sites with multiple contaminants, especially sites with multiple contaminants affecting the same target organ, may wish to use this website's [calculator](#). User's are encouraged to consult with risk assessors in that EPA Regional Office when evaluating or screening contamination at a site with multiple contaminants.

5.13 Deriving Soil Gas SLs

The air SLs could apply to indoor air from, e.g., a vapor intrusion scenario. To model indoor air concentrations from other media (e.g., soil gas, groundwater), consult with regional experts in vapor intrusion.

For more information on EPA's current understanding of this emerging exposure pathway, please refer to EPA's recent draft guidance Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance) (USEPA 2002) available on the web at: <http://www.epa.gov/correctiveaction/eis/vapor.htm>.

6. Using the Calculator

The [Calculator](#) can be used to generate site-specific SLs or PRGs. The calculator requires the user to make some simple selections. To use the calculator Select a landuse. Next, select whether you want Default or Site-specific SLs. Selecting default screening levels will reproduce the results in the generic [Generic Tables](#). Selecting Site-Specific will allow you to change exposure parameters. Now pick your analytes. To pick several in a row, depress the left mouse button and drag, then release. Or hold the Ctrl key down and select multiple analytes that are not in a row. Select the output option. Hit the retrieve button. If you selected Site-Specific, the next page allows you to change exposure parameters. Hit the retrieve button. SLs are being calculated. The first table presents the input parameters that were selected. The next table contains the screening levels. This table can be too big to print. The easiest way to manage this table is to move it to a spreadsheet or a database. To copy this table, hold the left mouse key down and drag across the entire table. when done, press Ctrl c to copy. Switch to a spreadsheet and press Ctrl v to paste.

Table 1. Standard Default Factors

Symbol	Definition (units)	Default	Reference
SLs			
SL _{res-air-ca}	Resident Air Carcinogenic (ug/m ³)	Contaminant-specific	Determined in this calculator
SL _{res-air-ca-vinylchloride}	Resident Air Carcinogenic Vinyl Chloride (ug/m ³)	Vinyl Chloride-specific	Determined in this calculator
SL _{res-air-mu}	Resident Air Mutagenic (ug/m ³)	Mutagen-specific	Determined in this calculator
SL _{res-air-nc}	Resident Air Noncarcinogenic (ug/m ³)	Contaminant-specific	Determined in this calculator
SL _{res-fish-ca-ing}	Resident Fish Carcinogenic (mg/kg)	Contaminant-specific	Determined in this calculator
SL _{res-fish-nc-ing}	Resident Fish Noncarcinogenic (mg/kg)	Contaminant-specific	Determined in this calculator
SL _{water-ca-ing}	Resident Tapwater Groundwater Carcinogenic Ingestion (ug/L)	Contaminant-specific	Determined in this calculator
SL _{water-ca-inh}	Resident Tapwater Groundwater Carcinogenic Inhalation (ug/L)	Contaminant-specific	Determined in this calculator
SL _{water-ca-tot}	Resident Tapwater Groundwater Carcinogenic Total (ug/L)	Contaminant-specific	Determined in this calculator

Re: Naples Public Health Evaluation – Process for Applying Multi-Floor Vapor Intrusion Attenuation Factors

Dear Dr. Gillooly:

The purpose of this memo is to present the process for determining when it is appropriate to apply multi-floor vapor intrusion attenuation factors (TetraTech, 2009) to soil gas data collected from residences in Naples, Italy. Multi-floor vapor intrusion attenuation factors account for the attenuation in airborne chemical concentrations that occurs between lower and higher floors or levels in a building and would potentially apply to situations where U.S. Personnel reside in living spaces on the 2nd floor¹ or higher. Multi-floor attenuation factors are applied in order to conservatively estimate the health risks associated with exposure to chemicals in indoor air resulting from vapor intrusion of soil gas.

Applicability

The multi-floor vapor intrusion attenuation factors presented in this memo are applicable to (TetraTech, 2009):

...multi-story apartments [*all multi-floor dwellings will be considered in this process including multi-floor houses, apartments, et cetera*] with concrete floors from subsurface sources may attenuate between floors. This memorandum is also useful for examining buildings with subsurface garages. Ultimately the attenuation factors between floors may be important in allowing residents to occupy spaces at higher floors in an apartment complex. Figure 1 shows a conceptualization for a two-story apartment. PCE vapor from a presumptive groundwater plume and/or contaminated soil volatilizes, diffuses through the unsaturated zone [*the area between the top of the water table and ground surface*], and migrates into the apartment through small cracks in the slab (or other available openings). Once vapors enter the first floor, the vapors mix with the indoor air, exchange with outdoor air, and potentially further intrude into the second story. This example apartment has a slab-on-grade foundation, which can be below grade as shown in this particular example. This example apartment unit also has no preferential pathway between floors, such as a stairwell. There is air exchange between the first and second floors, as well as air exchange between the outdoor air and each of the two stories. The vapor concentrations can be different between floors. This particular rendition of a two-story apartment and the surrounding environment is generic, and does not represent any specific apartment in Naples. Specific information about apartment construction and floor construction in Naples was not available for this course of this analysis. However, by specifying or calculating the size of the building, air exchange rates, building foundation types, and other data, this model can simulate different apartment types that use different construction materials. At present, site-specific data are unavailable to simulate a specific apartment; therefore, the present analysis is an approximation and only predicts indoor air concentrations within an order of magnitude.

¹ United States (U.S.) conventions for identifying floors in a building are used in this memo (i.e., the 1st floor is the ground floor and the 2nd floor is the floor immediately above the ground floor).

Proposed Approach for Applying Multi-Floor Vapor Intrusion Attenuation Factors to Soil Gas Data to Determine if Predicted Indoor Air Concentrations Results Pose an Acceptable or Unacceptable Risk

The approach/decision criteria for determining how/when multi-floor attenuation factors should be applied is described in the following bullets and summarized in Figure 2:

1. PIONEER will calculate health risks based on indoor air concentrations predicted by multiplying sub-slab or shallow (i.e., collected less than five feet below ground surface) near-slab soil gas results by the United States Environmental Protection Agency's (USEPA's) default vapor intrusion attenuation factor of 0.1 (USEPA, 2002). The USEPA's default attenuation factor of 0.1 accounts for the attenuation that occurs as vapors beneath a residence migrate into the lowest level of the building.
2. If the results are Acceptable, no further evaluation is necessary. If the health risks from Step 1 are Unacceptable, then a representative from the Environmental Health Information Center (EHIC) at U.S. Naval Hospital Naples will contact the resident by telephone regarding the soil gas results and ask specific questions about their residence (e.g., is it a multi-story structure [e.g., apartment], what floor do they live on, et cetera) and questions on the construction and arrangement of the building structure. See Telephone Notification Scripts attachment.
3. For the cases where the initial results were Unacceptable and contact was made with the resident, the information from the interview will be used to determine if the default attenuation factor (AF) is appropriate for estimating indoor air concentrations in the resident's living space, or if another AF (such as a multi-floor vapor intrusion attenuation factor (MFVIAF)) should be applied to calculate health risks based on indoor air concentrations. The following cases are possible:
 - a) The resident lives exclusively on the first floor directly above where a soil gas sample was collected. In this case, the transfer of volatile constituents across the building foundation and into the living space would be represented by the default AF of 0.1 applied to the soil gas sample results.
 - b) The resident lives on the second floor or higher and the building has an interior stairwell or elevator between levels without doors or structural elements (e.g., separate living spaces on each floor [apartments or condos]) that prevent indoor air from multiple floors from completely mixing. In this case, the transfer of volatile constituents across all of the levels of the building would be represented by the default AF of 0.1 (i.e., it is assumed that the MFVIAF for all inter-floor transfers within living spaces with interior stairwells or elevators is 1.0).
 - c) The resident lives on the second floor or higher and the building has an interior stairwell or elevator between levels with doors or structural elements (e.g., separate living spaces on each floor [apartments or condos]) that prevent indoor air from multiple floors from completely mixing. In this case, the transfer of volatile constituents across floors would be represented by a modified AF, calculated by using the default AF of 0.1 multiplied by the MFVIAF for each step of vertical transfer (0.12) assuming there is no site-specific information (e.g., the indoor air concentration on the 3rd floor would be calculated by multiplying the active soil gas concentration x 0.1 x 0.12 x 0.12).
 - d) The resident lives on the second floor or higher and there are no interior stairwells or elevators between levels. In this case, the transfer of volatile constituents across floors would be represented by a modified AF, calculated by using the default AF of 0.1 multiplied by the MFVIAF for each step of vertical transfer (0.12) assuming there is no site-specific information (e.g., the indoor air concentration on the 3rd floor would be calculated by multiplying the active soil gas concentration x 0.1 x 0.12 x 0.12).
 - e) The resident lives on the first or higher floor but the building has a sub-surface or first floor "open-air" garage (e.g., an open air parking garage or a non-routinely used storage space). In this case, the transfer of volatile constituents across floors would be represented by a modified AF, in the same manner as described in the previous example for each step of vertical transfer.

- Residences who fit cases b, c, d, or e in Step 3 are confirmed with a visit by a TetraTech representative, who will take photographs of the residence and collect site-specific information if possible and if not already documented at the time of soil gas sampling.
- If the visit confirms the resident's responses from Step 3, then PIONEER will recalculate the indoor air concentrations for the upper-floors of the structure (i.e., floors located above the 1st floor [ground floor in Italy]) using measured soil gas concentrations as follows:

$$IA_N = (SG_c \times 0.1) \times \left(\frac{1}{\left(\frac{X_f V_f}{Q_{f-1,f}} \right)} \right)^{N-1} \quad \text{Equation (1)}$$

Where:

IA_N = Indoor air concentration predicted on the N^{th} floor ($\mu\text{g}/\text{m}^3$).

SG_c = Sub-slab or shallow, (i.e., collected less than 5 feet below ground surface) near-slab soil gas concentration ($\mu\text{g}/\text{m}^3$).

0.1 = USEPA's default attenuation factor that is used to calculate the indoor air concentration on the 1st floor of the building based on the sub-slab/shallow soil gas concentration (unitless).

X_f = Air exchange rate of the N^{th} floor. If unknown use USEPA's default value of 6/day.

V_f = Volume of the N^{th} floor. If unknown use USEPA's default value of $(100 * (2.44\text{m}^3))$.

$Q_{f-1,f}$ = Air flow rate from any one floor to the next. If unknown use $180 \text{ m}^3/\text{day}$.

N = Floor where residence is located.

Note: If the USEPA's default inputs are used in Equation (1), then Equation (1) can be simplified to:

$$IA_N = (SG_c \times 0.1) \times (0.12^{N-1}) \quad \text{Equation (2)}$$

Examples

Below are examples of applying Equation (1) and Equation (2) to calculate indoor air concentrations based on measured sub-slab soil gas or shallow near-slab soil gas concentrations.

- Example of applying Equation (1) to calculate the indoor air concentration for a residence located on the third floor of a building with site-specific information:

$$IA_N = (200.5 \times 0.1) \times \left(\frac{1}{\left(\frac{10 \times 488}{200} \right)} \right)^{3-1} = 0.034 \frac{\mu\text{g}}{\text{m}^3} \quad \text{Example (1)}$$

Where:

IA_N = Indoor air concentration predicted on the N^{th} floor ($\mu\text{g}/\text{m}^3$).

SG_c = The sub-slab soil gas concentration is 200.5 ug/m^3 .

0.1 = USEPA's default attenuation factor that is used to calculate the indoor air concentration on the 1st floor of the building based on the sub-slab/shallow soil gas concentration (unitless).

X_f = Air exchange rate of the 3rd floor is 10/day.

V_f = Volume of the 3rd floor is $(100 * 4.88 \text{ m}^3)$.

$Q_{f-1,f}$ = The air flow rate between floors is $200 \text{ m}^3/\text{day}$.

N = The residence is located on the 3rd floor.

2. Example of applying Equation (2) to calculate the indoor air concentration for a residence located on the fifth floor of a building that does not have site-specific information.

$$IA_N = (200.5 \times 0.1) \times (0.12^{5-1}) = 0.0043 \frac{\text{ug}}{\text{m}^3} \quad \text{Example (2)}$$

Where:

IA_N = Indoor air concentration predicted on the Nth floor (ug/m^3).

SG_c = The sub-slab soil gas concentration is 200.5 ug/m^3 .

0.1 = USEPA's default attenuation factor that is used to calculate the indoor air concentration on the 1st floor of the building based on the sub-slab/shallow soil gas concentration (unitless).

0.12 = Upper-floor attenuation factor calculated using the following default parameters:

X_f = Air exchange rate of the Nth floor. If unknown use USEPA's default value of 6/day.

V_f = Volume of the Nth floor. If unknown use USEPA's default value of $(100 * (2.44 \text{ m}^3))$.

$Q_{f-1,f}$ = Air flow rate from any one floor to the next. If unknown use $180 \text{ m}^3/\text{day}$.

N = The residence is located on the 5th floor.

Telephone Notification Scripts for Environmental Health Information Center Notification of U.S. Personnel Due to PCE Contamination

Phase II F1 Inquiry Calls

(See Q&A on page 2)

Hello, this is Dr. Tim Halenkamp from the Naval Hospital's Environmental Health Information Center.

I'm calling on behalf of the Naples Public Health Evaluation and in particular, to discuss results of tap water and active soil gas samples that were collected from your residence.

The sampling preliminary results show that a chemical, **Tetrachloroethene** or **PCE**, was detected in active soil gas samples collected beneath or adjacent to your rental property at levels higher than the USEPA's health-based standards, which are the standards that we are using to assess health risks.

Let me first emphasize that there is no immediate health concern. We want to make sure that you have the sampling results and would like to meet with you one-on-one if you desire, to explain this in more detail and answer any questions you may have.

Based on the sampling results, there could be a potential risk of being exposed to PCE through *inhalation* of the chemical in indoor air (PCE vapors may enter the home from contaminated groundwater underneath through a process called vapor intrusion. [*Explain vapor intrusion if needed*].) However, to fully evaluate potential health risks in your home, we are calling to verify structural information about your building, because certain building structures can affect the potential risk from vapor intrusion.

Our database shows your home type is a [INSERT]. I'd like to go through a series of questions about your building:

- Is your building single story or multi story? On what floor is your residence? Is there an open, internal connection (e.g., open, internal stairway) between floors?
- Do you have a basement? Does the building have a basement? Is the basement connected to the upper floors via an open, internal stairway?
- Is there a ventilated garage beneath the living spaces?
- Do you know if there is a crawl space, or if the building is concrete slab-on-grade construction?
- Are there other American or NATO families living nearby? (Get Name, Address, Phone #)
- I would like to confirm your rank and rate? (If Active Duty)

[*Confirm Mailing Address*]

[*Confirm PRD*]

We appreciate your time and we'll review the information you have provided to determine the overall potential risk at your residence. We will follow up with you as soon as possible after our evaluation is complete.

Do you have any questions, or would you like to meet to discuss the sampling results?

[*Provide EHIC Contact Information*]

###

Q&A

**** If someone asks about relocation, use the following points ****

- **Will I have to relocate?**
 - Not necessarily. The information you provide us on the building structure will help us determine whether relocation is necessary, because certain building structures can affect the potential risk from vapor intrusion. (Refer to *Building Structures and Vapor Intrusion* fact sheet.)
 - Personnel in the Casal di Principe area were relocated, regardless of their building structure, because there is a suspected groundwater plume, that in the Navy's opinion, it requires investigation by the Italian authorities.
- **When will I know if I have to relocate?**
 - It will take some time to evaluate the information and determine whether relocation is confirmed. Please remember that there is no immediate health concern, and we will follow up with you as soon as possible.

Modeling and Mathematical Analysis of PCE Attenuation between Floors of Multi-Story Dwellings as it Applies to the Public Health Evaluation, Naples, Italy

Prepared by: Tetra Tech NUS

December 2, 2009

**This page has been left blank intentionally
to allow for double-sided printing.**

Introduction

The purpose of this memorandum is to examine how volatile organic compounds (VOCs), such as tetrachloroethene (PCE), that migrate into multi-story apartments with concrete floors from subsurface sources may attenuate between floors. This memorandum is also useful for examining buildings with subsurface garages. Ultimately the attenuation factors between floors may be important in allowing residents to occupy spaces at higher floors in an apartment complex. Figure 1 shows a conceptualization for a two-story apartment. PCE vapor from a presumptive groundwater plume and/or contaminated soil volatilizes, diffuses through the unsaturated zone, and migrates into the apartment through small cracks in the slab (or other available openings). Once vapors enter the first floor, the vapors mix with the indoor air, exchange with outdoor air, and potentially further intrude into the second story. This example apartment has a slab-on-grade foundation, which can be below grade as shown in this particular example. This example apartment unit also has no preferential pathway between floors, such as a stairwell. There is air exchange between the first and second floors, as well as air exchange between the outdoor air and each of the two stories. The vapor concentrations can be different between floors. This particular rendition of a two-story apartment and the surrounding environment is generic, and does not represent any specific apartment in Naples. Specific information about apartment construction and floor construction in Naples was not available for this course of this analysis. However, by specifying or calculating the size of the building, air exchange rates, building foundation types, and other data, this model can simulate different apartment types that use different construction materials. At present, site-specific data are unavailable to simulate a specific apartment; therefore, the present analysis is an approximation and only predicts indoor air concentrations within an order of magnitude.

Figure 1 - Conceptual model of two-story apartment over hypothetical PCE plume in groundwater. (Q_2^{in}, Q_1^{in} (Q_2^{out}, Q_1^{out}) = volumetric flow rates of outdoor air into (out of) the second and first floors, respectively; Q_{12} = volumetric flow rate from first floor to the second floor; Q_s = volumetric flow rate through soil; C_{d1}, C_{d2} = concentrations of PCE in first and second floors, respectively; L_{sog} = distance from bottom of slab to groundwater; L = distance from surface to groundwater; z = distance below bottom of slab on grade.

This memorandum examines two approaches that address the issue of PCE attenuation between floors:

1. Use of the Vapor Intrusion Model (ViM) (Mills et al., 2007) to simulate the entire process of plume volatilization, diffusion, intrusion, and mixing with indoor air. This approach predicts the ratios of concentrations between the first and second floors and the actual concentrations. ViM can analyze vapor intrusion into one-story or two-story apartments and can simulate multiple building types by using different parts of the code. For example, the part of the code that simulates a two-story slab-on-grade structure is different than the part of the code that simulates a crawl space. As such, ViM has numerous sub-models that are available as needed. Differing depths to groundwater and different soil properties are inputs to the model. ViM predicts floor-averaged concentrations and time-variable indoor air concentrations if concentrations in the plume are time variable. Mills et al. has updated ViM from the version discussed in Mills et al. (2007) to add slab-on-grade capabilities. The model is presently a research-grade model, and Mills et al. continue to add new features. Within the past year, Mills et al. have completed model results for single-story slab-on-grade applications for the United States Air Force. Mills et al. have presented many of the Air Force results at conferences around the United States over the past year. A portion of such a presentation is an attachment as a separate file to this technical memorandum (Attachment B). The presentation illustrates the accuracy that ViM attains when using site-specific data. It includes comparisons of the Johnson and Ettinger (J&E) model and ViM for a building with a slab-on-grade foundation. In that application, it was possible for the J&E model to predict indoor air concentrations within a factor of three of the observed data, while ViM predicted indoor air concentrations within about 10 percent. Both predictions were within the 5- to 95-percent confidence limit.
2. **Use of a mathematical approach that focuses only on predicting the concentration ratio between floors.** The mathematical approach is applicable to more than one-story or two-story apartments and uses a subset of the equations in ViM that pertains only to concentration changes between floors (that is, attenuation factors between floors). As the analysis below shows, this is a simpler approach than the full model described above if the analysis only requires defining attenuation factors. This is because the attenuation factors within buildings do not depend on plume concentration, depth to groundwater, or other geochemical factors.

Modeling Approach

Inputs to the ViM model are United States Environmental Protection Agency (EPA) default values, the foundation is slab-on-grade, and the chemical of interest is PCE. The reason for using the ViM model rather than the J&E model is that ViM can predict concentration differences between two floors and consequently the attenuation factors between the two floors, which is the objective of the study.

Figure 2 and Figure 3 illustrate ViM predictions of plume attenuation coefficients and PCE concentrations, respectively. In Figure 2, the three curves are as follows:

- The green curve represents attenuation from the groundwater to the subslab
- The blue curve represents attenuation from the groundwater to the first floor (indoor air)
- The red curve represents attenuation from the groundwater to the second floor (indoor air)

Note that the attenuation coefficients initially change rapidly (for the first few years) and then level off to constant values. The rapid initial change is during the period before PCE actually intrudes into the first floor. It is the constant (steady-state) values that are of interest here.

Figure 2 - Predicted Plume Attenuation Coefficients for PCE.

Figure 3. Predicted PCE concentration.

The ratio between the steady-state (year 2000 in the figure) attenuation factors from the blue and red lines (that is, the first and second floors) in this case is:

$$\frac{0.0001672}{2.09 \cdot 10^{-5}} = 8, \text{ and the attenuation factor ratio is } 1/8 \text{ or } 0.13$$

The model predicts that concentrations of PCE are lower by a factor of eight in the second story compared to the first for *this particular setting*. Note that even though attenuation factors attain a steady state, PCE concentrations do not (Figure 3) because the model assumes that PCE concentrations in the plume beneath the site are slowly decreasing. The fact that PCE concentrations are decreasing while the attenuation factors are approaching steady state may be helpful in streamlining any future analysis. This technical memorandum does not make a comparison to the J&E model because the J&E model does not simulate two-story buildings and time-variable plumes. However, Attachment B provides a comparison for a single-story slab-on-grade building.

Mathematical Analysis Based on a Subset of the Equations in ViM

The mathematical analysis that follows relates to PCE concentrations between stories. Equations (1) and (2) below are the same as programmed in ViM. As mentioned previously, over the past several years, Mills et al. have updated ViM. One of these updates is the two-story slab-on-grade option, so Mills et al. (2007) does not include those equations. Equation (1) is the chemical vapor mass balance equation for the second floor, which states that the change in mass in the second story equals the mass input from the ambient air and from the first floor minus the vapor that exits the second story, which depends on the air exchange rate. Attachment A includes this derivation. In mathematical symbols, for the second story:

$$V_{d2} \frac{\partial C_{d2}}{\partial t} = Q_2^{\text{in}} C_a + Q_{12} C_{d1} - X_{d2} V_{d2} C_{d2} \quad (1)$$

$$Q_2^{\text{in}} = X_{d2} V_{d2} - Q_{12} \quad (2)$$

Where:

$$\frac{\partial C_{d2}}{\partial t} = \text{time rate of change of PCE concentration on the second floor}$$

V_{d2} = volume of second floor

C_a = ambient or background PCE concentration

X_{d2} = air exchange rate for the second floor

Figure 1 shows all other variables.

The model includes the following two assumptions:

- The PCE concentration has attained steady state so the time-derivative in Equation (1) (the term on the left-hand side) is zero.
- The ambient or background air concentration of PCE is negligible compared to the PCE concentration in the intruding air. If this assumption is not valid, the actual background concentration can be a model input.

Assuming these assumptions are valid, the ratio of concentrations between the two floors is:

$$\frac{C_{d1}}{C_{d2}} = \frac{X_{d2} \cdot V_{d2}}{Q_{12}} \quad (3)$$

In the ViM simulation, the following data were used:

X_{d2} = 6/day (EPA's default value)

V_{d2} = (100)(2.44) m³ (EPA's default value)

Q_{12} = 180 m³/day (this value is proportionately less than the value shown in the application described in Mills et al. (2007) to account for a smaller apartment building with no preferential pathways). Note that Q_{12} is not the same as the subsurface soil gas flow rate (shown in Figure 1 as Q_s , which typically is in the range of 7.2 m³/day). Q_{12} is much higher than Q_s . Mills et al. (2007) derived the original value of Q_{12} from a tracer test..

Therefore,

$$\frac{C_{d1}}{C_{d2}} = \frac{(6)(100)(2.44)}{180} = 8.1, \text{ so the attenuation factor is } 1/8.1 = 0.12, \text{ approximately the}$$

same as predicted by ViM,

Where:

$$\frac{C_{d1}}{C_{d2}} = \text{concentration ratio between the first floor and second floor}$$

Because site-specific data for an individual unit are not available for this analysis, it is difficult to predict how site-specific features would change the results. The concentration ratio and attenuation ratio are the same as calculated by ViM, but the approach is less complex. Note that this approach does not require chemical property data such as Henry's Law Constant or depth to groundwater. The required data are air exchange rates for each floor, volume of the second story, and air flow from the first story to the second story. Note that the specific data assumptions in the model are the basis for the concentration ratio of 8.1:1 between stories. Although standard default values are available for air exchange rates, no such default data are available for the air flow rate between floors.

The approach for estimating the attenuation factor between the first floor and second floor, Equation (3), is applicable to more than two stories if using the same assumptions as between the first and second stories. Without showing the steps, the attenuation factor between the first story and Nth floor is:

$$\frac{C_{d1}}{C_{dN}} = \prod_{i=2}^N \frac{X_{di}V_{di}}{Q_{i-1,i}} \quad (4)$$

Where:

$$\frac{C_{d1}}{C_{dN}} = \text{concentration ratio between first and N}^{\text{th}} \text{ floors (attenuation factor is inverse of this)}$$

$\prod_{i=2}^N$ = multiplication operator

X_i = air exchange rate of the i^{th} floor

V_i = volume of i^{th} floor

$Q_{i+1,i}$ = volumetric flow rate from i^{th} to $(i+1)^{\text{th}}$ floor

If X_i , V_i , and $Q_{i+1,i}$ do not vary between floors, Equation (4) becomes:

$$\frac{C_{d1}}{C_{dN}} = \left(\frac{X_f V_f}{Q_{f-1,f}} \right)^{N-1} \quad (5)$$

Where:

X_f = air exchange rate of any of the floors

V_f = volume of any of the floors

$Q_{f-1,f}$ = air flow rate from any one floor to the next

As an example of an application of Equation (5), use the same data as before for a four-story building:

$$\frac{C_{d1}}{C_{d4}} = (8.1)^3 = 530, \text{ so the attenuation factor is } 1/530$$

For this example, the first-floor concentration is 530 times greater than the concentration on the fourth floor, assuming all the assumptions made earlier are valid.

The lower limit of Equation (5), the concentration ratio for N stories, is theoretically close to unity. This would occur **only** if all air flow into a floor were to come from the floors below (a very unlikely situation) and not from exchange with outdoor air or from the operation of systems such as Heating, Ventilating, and Air Conditioning (HVAC) systems.

Summary

This memorandum describes two approaches for calculating concentration ratios (or attenuation factors) between floors of an apartment building. One of the approaches is to use the ViM model that simulates migration of vapors between floors in a two-story building. The second approach is to solve mathematically the chemical mass balance equations for each of the floors of the building. The equations used are the same as in ViM for the second floor, and these equations are applicable to additional stories. Comparison of the two approaches (modeling and mathematical formulas) for a second-story apartment showed that predicted results were the same.

As long as the goal of the study is to calculate the ratio of attenuation factors between floors and not the concentrations themselves, the simpler mathematical approach is the preferred choice because implementation requires less data. At best, the use of EPA default data and lack of site-specific data limit the interpretation of the approaches presented here to an order-of-magnitude screening-level analysis. If site-specific data are available, their review and comparison with data using the current approaches will determine their applicability for future modeling efforts.

The attenuation factor between floors derived in this technical memorandum will allow the public health team to determine whether to allow residents to occupy spaces on higher floors in an apartment building. Applying an attenuation factor of 0.1 to active soil gas contaminant concentrations predicts an estimated indoor air concentration for the ground floor. Applying an attenuation factor of 0.12, as derived in this technical memorandum, to the estimated indoor air contaminant concentrations predicts an estimated indoor air concentration on the next higher floor. In some cases, residents may live on the higher floor of a building where field personnel collected active soil gas data. If the estimated ground floor indoor air concentrations were unacceptable, use of the between-floors attenuation factor may help the public health team demonstrate that higher floor indoor air concentrations could be acceptable.

All models have limitations. Before choosing a model for an analysis, the modeler must review the assumptions which form the basis of the model to ensure they are consistent with and applicable to the situation. If not, then the modeler must either choose another model or possibly undertake a field study.

Attachment A

Derivation of Equations

This attachment provides more details of the development of Equations (1) through (5) presented in the technical memorandum, Modeling and Mathematical Analysis of PCE Attenuation Between Floors of Multi-Story Dwellings as it Applies to the Public Health Evaluation, Naples, Italy. Equation (1) is a mass balance of a chemical (PCE in this case) on the second floor of the apartment. In more conceptual terms, Equation (1) is equivalent to:

$$\frac{\Delta M_2}{\Delta t} = M_{in_2} - M_{out_2} \quad (\text{A-1})$$

Where:

M_{in_2} = mass of PCE that enters the building at second story over a time period of Δt
(from all sources)

M_{out_2} = mass of PCE that leaves the building at floor level 2 over time period Δt
(for all sinks)

M_2 = mass of PCE in building at floor level 2

The mass rate that PCE enters floor level 2 depends on the mass entering from ambient air, the flow rate of the ambient air, and the flow rate into the building from the floor below and from any other source. Based on this information:

$$M_{in_2} = Q_2^{in} C_a \quad (\text{A-2})$$

$$M_{out_2} = X_{d2} V_{d2} C_{d2} \quad (\text{A-3})$$

$$Q_2^{in} = X_{d2} V_{d2} C_{d2} \quad (\text{A-4})$$

$$M_2 = V_{d2} \cdot C_{d2} \quad (\text{A-5})$$

Where:

$$\frac{\Delta M_2}{\Delta t} = \text{time rate of change of PCE mass on the second floor}$$

$$V_{d2} = \text{volume of second floor}$$

$$C_a = \text{ambient or background PCE concentration}$$

$$X_{d2} = \text{air exchange rate for the second floor}$$

$$C_{d2} = \text{concentration of PCE on second floor}$$

$$C_{d1} = \text{concentration of PCE on first floor}$$

Combining Equations (A-2) through (A-5) with (A-1), the following results:

$$V_{d2} \frac{\Delta C_{d2}}{\Delta t} = Q_2^{in} C_a + Q_{12} C_{d1} - X_{d2} V_{d2} C_{d2} \quad (\text{A-6})$$

Equation (A-6) is the same as Equation (1) in the memorandum, except the left-hand side in Equation (1) denotes the instantaneous change. From a practical point of view, this makes no difference as we only consider a steady-state condition when that term is zero.

To develop Equation (3), assume the ambient concentration of PCE (C_a) is zero, then Equation (A-6) becomes at steady state:

$$0 = 0 + Q_{12} C_{d1} - X_{d2} \cdot V_{d2} \cdot C_{d2} \quad (\text{A-7})$$

By rearranging (A-7) in terms of the ratio between floors, the following results:

$$\frac{C_{d1}}{C_{d2}} = \frac{X_{d2} \cdot V_{d2}}{Q_{12}} \quad (\text{A-8})$$

This equation is identical to Equation (3) in the memorandum.

For apartments with more than two floors, the logic to derive (A-8) is the same:

$$\frac{C_{d2}}{C_{d3}} = \frac{X_{d3} \cdot V_{d3}}{Q_{23}} \quad (\text{A-9})$$

$$\frac{C_{d3}}{C_{d4}} = \frac{X_{d4} \cdot V_{d4}}{Q_{34}} \quad (\text{A-10})$$

Multiply (A-8) by (A-9) by (A-10):

$$\frac{C_{d1}}{C_{d2}} \cdot \frac{C_{d2}}{C_{d3}} \cdot \frac{C_{d3}}{C_{d4}} = \frac{X_{d2} \cdot V_{d2}}{Q_{12}} \cdot \frac{X_{d3} \cdot V_{d3}}{Q_{23}} \cdot \frac{X_{d4} \cdot V_{d4}}{Q_{34}}$$

or

$$\frac{C_{d1}}{C_{d4}} = \prod_{i=2}^4 \frac{X_{d_i} \cdot V_{d_i}}{Q_{i-1,i}} \quad (\text{A-11})$$

Equation (A-11) is the same as Equation (4) (for two stories). This equation does not show the generalization to N stories.

If exchange rates, floor volumes, and flow rates between stories is constant, Equation (A-11) becomes:

$$\frac{C_{d1}}{C_{d4}} = \prod_{i=2}^4 \frac{X_d \cdot V_d}{Q_{f-1,f}} = \left(\frac{X_d V_d}{Q_{f-1,f}} \right)^3 \quad (\text{A-12})$$

Where:

X_d = air exchange rate of any of the floors

V_d = volume of any of the floors

$Q_{f-1,f}$ = air flow rate from any one floor to the next

Equation (A-12) generalizes to Equation (5) for N floors.

TETRA TECH

Conclusions from the Alternative Modeling Approaches

- Indoor air TCE best correlated with:
 - Arithmetic average sub-slab soil gas measurements as source term
 - Predicted indoor air concentrations using near-slab and sub-slab soil gas differ by only about 10%
- Groundwater equilibrium vapor concentrations less appropriate source term
 - Predicted indoor air levels averaged 7 times lower than measured concentrations

SUMMARY STATISTICS FOR AMBIENT AIR COLLECTED IN NAPLES, ITALY AND IN THE U.S.

1.1 Overview

This appendix presents summary statistics for ambient air samples that were collected in Naples, Italy as part of the year-long ambient air sampling and monitoring program (07/09/2008 to 07/08/2009) and at individual residences. In addition, summary statistics are presented for ambient air samples collected from six cities in the United States by the United States Environmental Protection Agency (USEPA) (USEPA, 2007). These data were used to develop exposure point concentrations for (EPCs) for ambient air that are applicable to all residences located within a study area. The data are organized by study area as follows:

- Table C-1 – Study Area 1 – Joint Forces Command (JFC) North Atlantic Treaty Organization (NATO) Site
- Table C-2 – Study Area 2 – U.S. Consulate
- Table C-3 – Study Area 3 – Capodichino
- Table C-4 – Study Area 4 – Carney Park (Carney Park is located within Study Area 1 but was used to evaluate Study Area 4)
- Table C-5 – Study Area 5 – Lago Patria Receiver Site/Parco Artemide
- Table C-6 – Study Area 6 – Gricignano Support Site
- Table C-7 – Study Area 7 – Parco Eva (US Navy-Leased Parco)
- Table C-8 – Study Area 8 – Villa (Home leased by the US Navy for the Public Health Evaluation)
- Table C-9 – Study Area 9 – Parco Le Ginestre (US Navy-Leased Parco)
- Table C-10 – USEPA 2007 Air Toxics Database

Unlike soil, individual tap water samples, and soil gas samples that were collected as part of the Naples Public Health Evaluation, multiple ambient air samples were collected as part of the year-long ambient air study in the Campania Region from the air monitoring stations in each study area from 07/09/2008 to 07/08/2009. Consequently, EPCs for ambient air were determined by calculating the 95% upper confidence limit (UCL) on the mean concentration for all samples collected in each study area (individual ambient air samples that were collected from select residences in the study areas were also included in the calculations). The 95% UCL on the logarithmic mean concentration (calculated using the H-statistic via the Land method) was used as the EPC if the data appeared to be lognormally distributed (5% significance level), the 95% UCL on the arithmetic mean was used if the data appeared to be normally distributed (5% significance level). If the distribution could not be determined (i.e., the data were neither normally or lognormally distributed), the 95% UCL on the arithmetic mean was used as the EPC, which is typically a reasonable assumption for data sets with over 30 data points because they tend to approximate a normal distribution. The maximum detected concentration was used if the 95% UCL on the logarithmic mean concentration or 95% UCL on the arithmetic mean concentration exceeded the maximum detected concentration. Nondetects were included in the statistical calculations using a

surrogate value of half the detection limit. Prior to performing the statistical analysis on the ambient air data, the data were pre-processed as described below:

- Field duplicate results were averaged based on the following decision rules:
 - If both results were detected, then the average concentration was calculated
 - If one result was detected and the other result was not detected, then the detected result was used as the concentration for the sample.
 - If both results were not detected, then the lower of the detection limits was used as the quantitation limit for the sample.
- In instances where a COPC's result was reported by the laboratory using different analytical methods, only one result was retained in the analytical database based on the following decision rules:
 - If both results were detected, then the higher of the two results was used as the concentration for the sample.
 - If one result was detected and the other result was not detected, then the detected result was used as the concentration for the sample.
 - If both results were not detected, then the lower of the detection limits was used as the quantitation limit for the sample.

FEBRUARY 2010 – REV: 03

SECTION P.1 – PREFACE

P.1.1 INTRODUCTION

For more than a decade, the Campania Region of Italy has experienced numerous challenges associated with trash collection, uncontrolled open burning of uncollected trash, and widespread dumping of waste, including chemical and other potentially-hazardous waste (see Figure P-1). In response to the concerns of the United States Navy (USN) and their civilian personnel and families that these poor waste-disposal practices (dumping and open-burning of uncollected trash and dumping of illegal waste) present a risk to USN personnel (active duty, civilians, and their families) who are residing in this area, the Navy and Marine Corps Public Health Center (NMCPHC) is performing a Public Health Evaluation (PHE) in the Naples province which is located in the Campania Region of Italy (see Figure P-2). Because a comprehensive PHE will take over one year to complete, the USN has implemented a phased approach for this study.

The Naples PHE (NPHE) began with a pilot study, which included collecting soil and tap water samples from seven homes in the greater Naples area of the Campania Region. Air monitoring was also conducted at two of the seven residences. The pilot study was conducted to identify problems associated with contacting residences and landlords, collecting samples, shipping samples to the laboratory, analyzing the data, evaluating the results, and communicating the results to the residents and to provide an opportunity to streamline those activities before conducting a larger study.

After completion of the pilot study, sampling began at more than 130 homes in the greater Naples area of the Campania Region (Phase I of the NPHE). The residences included single-family homes and apartments occupied by United States (US) personnel. In addition, approximately 30 U.S. government-related properties were sampled in Phase I of the NPHE.

Sampling results identified chemicals of potential concern (COPCs) that were detected in soil gas at concentrations that exceeded US Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs) (USEPA, 2009). These soil gas concentrations may represent a subsurface (soil or groundwater) vapor intrusion (VI) source that could potentially impact indoor air.

As part of Phase II of the NPHE, ambient air, soil, soil gas, and tap water samples were collected at residences and other government-related locations in the greater Naples area of the Campania Region. Approximately 2,000 properties are eligible for Phase II sampling, including tenants, installations, three government parks, empty residences, and approximately 10 homes in areas not currently on the housing list. Approximately 200 properties have been sampled during Phase II. Table P-1 summarizes the number of samples being collected in each study area for Phase II.

The purpose of this Technical Memorandum (Memo) is to evaluate multimedia environmental data collected as part of the NPHE to identify inhalation COPCs that may be associated with a subsurface VI source versus other Non-VI sources (i.e., above-ground sources in ambient air and/or indoor air). It was not possible to differentiate between chemicals potentially resulting from poor waste disposal practices (dumping/burning of trash and hazardous waste) and other sources in this evaluation. Hence the focus of this Memo is to determine whether or

not chemical concentrations found in soil gas are associated with subsurface VI sources that could contribute to VI in overlying buildings. This distinction is important so that the risks can be calculated appropriately and educated, appropriate risk-management decisions can be made.

Note: Uncontrolled waste-disposal practices (dumping and open-burning of uncollected trash and dumping of illegal waste) impact the environment both above-ground (ambient air/indoor air) and in the subsurface (soil and groundwater). Other above-ground sources of chemicals include typical urban contaminant sources such as nearby gasoline stations, automobile exhaust, dry cleaners, fuel storage tanks, diesel motors and generators, industrial facilities, agricultural practices, and landfills. Other subsurface VI sources include leaking underground storage tanks, leaking storage vessels, landfills, spills and releases associated with industrial, commercial and agricultural activities, and disposal of contaminated water through septic systems.

This Preface is intended to describe in detail the various components that were considered in the soil gas data evaluation presented in this Memo. Specifically, this Memo incorporates and builds on information presented in documents that were written and accepted as part of the NPHE. The following two documents provided a majority of the basis for this Memo.

1. **The Phase I Screening Risk Evaluation (SRE)** (PIONEER, 2009). The purpose of the Phase I SRE was to determine whether or not there were any potential health impacts associated with exposure to surface soil, indoor air, tap water, and ambient (outdoor) air to USN personnel (active duty, civilians, and their families), residing in the greater Naples area of the Campania Region.
2. **The Project-Specific Quality Assurance Project Plan (QAPP). Environmental Testing Support Assessment Phase II** (Tetra Tech 2008). The purpose of the QAPP is to "*Utilize the Environmental Testing Support Assessment (ETSA) to define/characterize human health risks to US Department of Defense (DoD) and Consulate personnel living in the Campania Region as evaluated by exposure to air, soil, soil gas, and tap water as a result of trash, trash burning, and dumping of waste.*" The QAPP is the road map for the NPHE and is considered a "living" document, which means that it should, and will likely need to, be updated as the NPHE progresses and new, more up-to-date information becomes available. At this time (i.e., February 2010), there are some components of this soil gas Memo that will deviate from the QAPP. These items are addressed at the end of the Section P.1.1.6.

To aid the reader, important information and concepts from these two documents are summarized below. This information provides context that is necessary to evaluate and interpret the results and conclusions presented in this Memo.

P.1.1.1 Study Areas

The NPHE focused on the Naples area of Campania where USN personnel work and live (see Figure P-1). Since the geographical area being investigated was very large, the region was segregated into nine geographical study areas with a focus on identifying areas of residential properties located near known or suspected waste sites (Figure P-1). The nine study areas are listed below, with the U.S. government-related facilities located within the study area identified, and the approximate size of the study area in square miles. Combined, the study areas comprise approximately 395 square miles:

- Study Area 1: Joint Forces Command (JFC) North Atlantic Treaty Organization (NATO) Site (approximately 30 square miles)
- Study Area 2: U.S. Consulate (approximately 15 square miles)
- Study Area 3: Capodichino (approximately 95 square miles)
- Study Area 4: Carney Park (approximately 30 square miles) (Carney Park is located within Study Area 1 but was used to evaluate Study Area 4)
- Study Area 5: Lago Patria Receiver Site/Parco Artemide (approximately 80 square miles)
- Study Area 6: Gricignano Support Site (approximately 45 square miles)
- Study Area 7: Parco Eva (USN-Leased Parco) (approximately 20 square miles)
- Study Area 8: Villa (Home leased by the USN for the NPHE) (approximately 30 square miles)
- Study Area 9: Parco Le Ginestre (USN-Leased Parco) (approximately 50 square miles)

P.1.1.2 Conceptual Site Model

The Conceptual Site Model (CSM) presented in the QAPP and SRE was a significant building block for this Memo. The CSM provides an understanding of the potential for exposure, under current and future land uses, to chemicals within a study area based on the source(s) of contamination, the release mechanism(s), the exposure pathway(s), and the receptor(s). The CSM for the site is presented on Figure P-3 and discussed below.

The sources and release/transport mechanisms of contamination in the nine study areas are:

- **Source of contamination – Trash Dumped and Burned Throughout the Campania Region**
 - Release/transport mechanisms:
 - Vapors and particulates released to the air via burning trash are then transported via wind
 - Particulates in the air are deposited onto soil and surface water
 - Chemicals deposited on soil may leach from soil into underlying groundwater
- **Source of contamination – Legal and Illegal Dumping of Waste (including chemical waste)**
 - Release/transport mechanisms:
 - Chemicals deposited on soil may leach from soil into underlying groundwater.
 - Volatile chemicals may volatilize from soil and/or groundwater into ambient air or the indoor air of buildings
 - Particle-bound chemicals in soil may be transported into the air via erosion due to wind
- **Source of contamination – Point (e.g., exhaust from power plants and factories) and Non-Point (e.g., automobile exhaust) Combustion Sources in the Campania Region**
 - Release/transport mechanisms:
 - Vapors and particulates released into the air are then transported via wind
 - Particulates in the air are deposited onto soil and surface water
 - Chemicals deposited on soil may leach from soil into underlying groundwater

The complete exposure pathways include the following:

- Inhalation of vapors and particulates in ambient air emitted from combustion sources (e.g., burning of trash, exhaust from power plants and factories, and automobile exhaust)
- Incidental soil ingestion (where soil samples were collected)
- Dermal contact with soil (where soil samples were collected)

- Inhalation of vapors and particulates in air emitted from soil
- Inhalation of vapors in indoor air associated with vapor intrusion from groundwater and/or soil
- Ingestion of tap water, which may be provided by the city and/or by a well on the property
- Inhalation of vapors in indoor air associated with household uses of tap water (e.g., showering & washing dishes)

The following potentially-exposed populations living and/or working in the study areas were evaluated:

- USN personnel
- U.S. Civil Service personnel and their families
- Department of Defense (DoD) and DoD Dependant Schools (DoDDS) personnel and their families
- U.S. State Department personnel and their families

The following potentially-exposed populations living and/or working in the study areas were not evaluated:

- Other private U.S. citizens and their families
- Italian citizens
- Other, non-Italian, foreign nationals

P.1.1.3 Identification of Risk-Based Screening Levels for Soil Gas

As stated in the QAPP and SRE, risks will be computed by comparing exposure point concentrations (i.e., the concentration of a chemical at the location of potential contact with the receptor [i.e., individual]) for soil, tap water, soil gas, and ambient air with standard USEPA 30-Year Residential RSLs (USEPA, 2009) (see Table P-2). Only soil gas RSLs are presented here because soil gas is the primary focus of this Memo. Soil gas RSLs were derived, as specified in both the Appendix C of the QAPP and the SRE report, from the USEPA's standard, 30-Year Residential RSLs for ambient air¹ by dividing the ambient air RSLs by the USEPA's default vapor attenuation factor (VAF) of 0.1 (USEPA, 2002). The resulting RSLs are considered protective of human health because USN tour lengths are typically three to six years. However, because DoD school teachers can remain for 30 years or longer, the USEPA's 30-year standard residential ambient RSLs are used as the basis of the resulting soil gas RSLs.

Inhalation risks associated with VI of chemicals in soil gas to indoor air can vary by orders of magnitude depending on the degree of the attenuation that occurs between soil gas and indoor air. Subsurface conditions and building characteristics vary across the nine study areas, and because building access was not always achievable, some soil gas samples were collected sub-slab and some were collected outside of the building (near-slab). However, all soil gas sample concentrations, regardless of how they were collected, are compared to RSLs that were calculated using the USEPA's default VAF (α) of 0.1 (normally used for sub-slab soil gas), which is also the VAF specified in the QAPP. Applying a VAF of 0.1 is considered a very conservative assumption because VAFs can range from 0.1 to 0.0001 (or more) depending on groundwater-specific/soil-specific/building-specific characteristics (USEPA, 2008a). The use of a 0.1 VAF will likely overestimate the actual risk associated with VI, especially for samples that were collected near slab versus sub-slab. However, because groundwater-specific/soil-specific/building-specific characteristics are not available in Naples, for this screening assessment it is not appropriate to develop site-specific VAFs that might be less conservative.

P.1.1.4 Methodology for Calculating Risks

The cumulative human health risks based on soil gas at each sample location will be combined with the risk results from soil and tap water to calculate the cumulative risk at each location. Risks are estimated according to the calculations identified in the QAPP and SRE as follows.

Analytical data from soil, soil gas, tap water, and ambient air samples are compared to RSLs. Chemical exceedance factors (EFs) are calculated by dividing the exposure point concentration by the RSL using the following equations:

$$EF = \frac{C_{Soil}}{ScreeningCriterion} \quad EF = \frac{(C_{SoilGas} \times \alpha)}{ScreeningCriterion} \quad EF = \frac{C_{TapWater}}{ScreeningCriterion} \quad EF = \frac{Conc_{AmbientAir}}{ScreeningCriterion}$$

Where:

Parameter	Description
SOIL	
C _{Soil}	Concentration in surface soil sample
Screening Criterion	USEPA Residential-Based RSLs for soil, calculated based on a carcinogenic risk of 1E-06 and/or a Hazard Quotient (HQ) of 1 – assuming a 30-year exposure duration
SOIL GAS	
C _{SoilGas}	Concentration in the soil gas sample
VAF (α)	Default USEPA VAFs used to predict indoor air concentrations based on soil gas concentrations. A VAF of 0.1 used in the calculations.
Screening Criterion	USEPA Residential-Based RSLs for air, calculated based on a carcinogenic risk of 1E-06 and/or a Hazard Quotient (HQ) of 1 – assuming a 30-year exposure duration
TAP WATER or Irrigation Well Water	
C _{TapWater}	Concentration in the tap (or irrigation well) water sample.
Screening Criterion	<ul style="list-style-type: none"> USEPA Residential-Based RSLs for tap water, calculated based on a carcinogenic risk of 1E-06 and/or a HQ of 1 – assuming a 30-year exposure duration USMCLs
AMBIENT AIR	
Conc _{AmbientAir}	Ambient air risks are determined by calculating the 95% upper confidence limit (UCL) on the mean per Study Area. The Log 95% UCL on the mean is used if the data are lognormally distributed, the 95% UCL is used if the data are normally distributed. The maximum detected concentration is used if the Log 95% UCL or 95% UCL exceed the maximum detected concentration.
Screening Criterion	<ul style="list-style-type: none"> USEPA Residential-Based RSLs for air, calculated based on a carcinogenic risk of 1E-06 and/or a HQ of 1 – assuming a 30-year exposure duration NAAQS

Cumulative cancer exceedance factors (CCEFs) and cumulative noncancer exceedance factors (CNCEFs) for each sample are calculated by summing the individual cancer EFs (CEFs) and noncancer EFs (NCEFs) for COPCs based on RSLs. A CEF and NCEF of 10 indicate that exposure to soil, soil gas, or tap water could potentially result in a cumulative cancer risk of 1E-05 and a Hazard Index (HI) of 10, respectively.

None of the inhalation COPCs identified in this Memo will be removed from the risk evaluation. Three separate cumulative risk calculations will be performed in the risk assessment (see below), but only the results of the incremental risk calculations will be discussed in the risk assessment and used for risk management decisions:

1. **Total Risk** – Total risk represents the risk for all COPCs (background and incremental)

2. **Background Risk** – Background risk is the risk for COPCs that are naturally occurring in the environment (i.e., inorganic elements) or the result of anthropogenic activities. Background data for soil in the Campania Region were found in the scientific literature (PIONEER, 2009).
 - For soil gas, no suitable background concentrations could be located in the scientific literature. Therefore, there are no background risks for soil gas.
 - For ambient air, no suitable background concentrations for the Campania Region could be located in the scientific literature. Therefore, the 95% UCL on the mean³ from data obtained for six U.S. cities (i.e., San Diego, California, Los Angeles, California, Seattle, Washington, Houston, Texas, Midlothian, Texas, and Washington DC) from 2007 U.S. EPA Air Toxics Database (USEPA, 2007) will be used to represent background concentrations from typical urban air.
3. **Incremental Risk** – Incremental risks will be calculated by subtracting the background risks (i.e., risks for COPCs that are naturally occurring in the environment or the result of anthropogenic activities) from the total risks. Risk management decisions will be based on incremental risks.
 - For ambient air, incremental risks are risks that could be related to trash burning, trash dumping, or other point and non-point sources, and not related to natural background or anthropogenic sources that are typical of urban environments. For ambient air, these are the risks for chemicals where the Study Area specific 95% UCL ambient air concentration exceeds the 95% UCL from the six cities in the 2007 U.S. EPA Air Toxics Database (USEPA, 2007).
 - For soil gas, COPCs detected in soil gas will be classified into the following three groups so that the risks can be calculated appropriately:
 - **Non-VI COPCs** – COPC(s) associated with above-ground contaminant sources (i.e., ambient air and/or “typical” indoor air) and not with subsurface VI. Risks for these COPCs will be calculated using ambient air results at all locations.
 - **Localized VI COPCs** – COPC(s) potentially associated with a subsurface VI source within a specific geographical area. Most COPCs fall into this category because subsurface VI is commonly associated with a localized release. This group also includes COPCs for which the determination was inconclusive. Risks for these COPCs will be calculated using either soil gas results or ambient air results depending on the determination at that location.
 - **Global VI COPCs** – COPC(s) associated with a subsurface VI source at all locations. For these COPCs, there must be compelling evidence to indicate that subsurface VI is a study-wide issue. Risks for these COPCs will be calculated using soil gas results at all locations.

P.1.1.5 Risk Management Categories for Evaluating Incremental Risks

Risk management categories were determined in the QAPP (Tetra Tech, 2008), and SRE (PIONEER, 2009) results were measured against these categories. These categories are also applicable to soil gas results from this Memo. The SRE characterized the potential health risks associated with living at a residence for 30 years. This is generally a conservative assumption because tour lengths typically range from three to six years. Consistent with the SRE, the risk evaluation results (incremental risks) will be placed into one of two categories:

² Soil gas results are not directly comparable to USEPA RSLs for air (USEPA, 2008b). They must be multiplied by a VAF of 0.1, which results in a predicted indoor air concentration that can be compared directly to USEPA RSLs.

³ The Log 95% UCL on the mean is used if the data are lognormally distributed, the 95% UCL is used if the data are normally distributed. The maximum detected concentration is used if the Log 95% UCL or 95% UCL exceed the maximum detected concentration.

1. Acceptable Risk – The noncancer and cancer risks at this residence are considered Acceptable based on the criteria presented below.
2. Unacceptable Risks – The noncancer and cancer risks at this residence are considered Unacceptable based on the criteria presented below.

Risk-Management Categories

Criteria/Actions	<u>Acceptable</u> Incremental Risks	<u>Unacceptable</u> Incremental Risks
Risk Criteria for Residences Using Tap Water for Drinking, Food Preparation, Cooking, Brushing Teeth, and Making Ice.	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). Applies to all chemicals. • Concentration less than or equal to USEPA NAAQS (ambient air). 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). Applies to all chemicals. • Concentration greater than the USEPA NAAQS (ambient air).
Risk Criteria – for Residences NOT Using Tap Water for Drinking, Food Preparation, Cooking, Brushing Teeth, and Making Ice	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). • Concentration less than or equal to USEPA NAAQS (ambient air). 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). • Concentration greater than the USEPA NAAQS (ambient air).

Notes:

NCEFs are calculated by dividing the exposure point concentrations by noncancer-based RSLs.
 CEFs are calculated by dividing the exposure point concentrations by cancer-based RSLs.
 The individual NCEFs and CEFs are summed to provide the total CNCEF and total CCEF, respectively.
 An NCEF of 1 corresponds to a Hazard Index of 1.
 A CEF of 1 corresponds to a cancer risk of 1E-06 (one in a million). A CEF of 10 corresponds to a cancer risk of 1E-05 (one in a 100,000).
 NAAQS = United States National Ambient Air Quality Standards.
 USMCLs = United States Maximum Contaminant Levels (40 CFR Part 141) (<http://www.epa.gov/safewater/contaminants/index.html>)
 This evaluation also includes RSLs for evaluating soil and soil gas, as appropriate.

P.1.1.6 Deviations from the QAPP

P.1.1.6.1 Background Values

The QAPP is a "living document" and was intended to be revised, if necessary, as additional information became available. Therefore, the QAPP should be revised to clarify the approach for calculating the risks associated with VI-related COPCs. The approach in this Memo regarding background data deviates from the QAPP, which states, *“For soil gas, all chemicals detected will be assumed to originate from a contamination source”* and *“For air, reference values from U.S. (EPA air toxics monitoring network, 2007) will be used as comparison values.”*

At this time, background ambient air concentrations for Naples have not been identified. Therefore, the 95% UCL values for data from the 2007 U.S. EPA Air Toxics Database (USEPA, 2007) will be used to represent background concentrations from typical urban air to calculate incremental risks for ambient air (see Section P.1.1.4).

One of the key concepts that is presented in this Memo is that concentrations of COPCs in ambient air and/or indoor air can significantly influence sub-slab soil gas and shallow, near-slab soil gas samples (i.e., for some COPCs these samples are actually measuring ambient air concentrations and not a VI source). With respect to soil gas, the QAPP does not distinguish between the contaminant source originating from above ground (ambient air and/or indoor air) or below-ground (subsurface VI). The multi-media analytical data provide evidence that, for some COPCs, the soil gas samples were impacted by volatile COPCs that were present in ambient air (e.g., acrolein) and/or indoor air. This is also supported by information in the scientific literature regarding the transport of oxygen and other volatile chemicals into the soil column (Scott, 2000; Lundegard et. al., 2008).

Additional Properties	10	15
Totals	225	165

Note:

¹The Project Team decided to add a small number samples for additional properties in areas not previously sampled. This would add to the confidence with which decisions about the previously unsampled areas could be made. The selected number of samples was 10 and represents an attempt to improve decision making across the nine study areas and to provide an initial indication of the levels of contamination in these areas that were not previously sampled. These additional properties will be identified prior to Phase II sampling (Tetra Tech, 2008).

Technical Memorandum: Identification of Chemicals in Soil Gas That May Be Associated with Vapor Intrusion

1.1 INTRODUCTION

The Navy and Marine Corps Public Health Center (NMCPHC) is performing a Public Health Evaluation (PHE) in the Campania Region of Italy in response to concerns by the United States (U.S.) Navy (USN) and their civilian personnel and families that poor waste disposal practices (dumping and open burning of uncollected trash and dumping of illegal waste) present a risk to USN personnel (active duty, civilians, and their families) who are residing on the economy in the Naples Province of Campania. Because the geographical area being investigated is very large (approximately 395 square miles), the region has been segregated into nine geographical study areas (see the Preface to this Memo for identification of the study areas) for evaluation purposes.

During the Naples PHE (NPHE), chemicals of potential concern (COPCs) were detected in soil gas at concentrations that exceeded United States Environmental Protection Agency (USEPA) inhalation Regional Screening Levels (RSLs) (USEPA, 2009). These soil gas concentrations may represent a subsurface (soil or groundwater) vapor intrusion (VI) source that could potentially impact indoor air.

VI is the migration of volatile organic compounds (VOCs) from the subsurface into overlying buildings. Under some conditions, VOCs in soil or groundwater may migrate via soil gas into nearby basements, buildings, and other enclosed spaces. However, not all chemicals detected in soil gas are associated with VI from a source in soil or groundwater. Some of the chemicals detected in soil gas may be associated with sources in ambient air and/or indoor air that are unrelated to subsurface contamination. For example, chemicals in ambient air can migrate down into the soil column via diffusion and advection (Scott, 2000). Oxygen transport from the atmosphere to soil gas beneath concrete slabs and adjacent to concrete slabs has been documented by investigators researching vapor migration of aerobically-biodegradable compounds (i.e., petroleum hydrocarbons) (Lundegard et. al., 2008). Both empirical data and modeling results have shown that VOCs detected in subsurface vapor samples can originate from indoor sources, migrating in response to pressure gradients via advective flow down through building foundations (McHugh et. al., 2006). The depth to which ambient and/or indoor air migrates downward into the soil column is limited by many of the same factors that affect upward diffusion and advection of soil gas, but the impact is typically more pronounced on shallow soil gas samples (i.e., the concentrations of chemicals that are associated with ambient air that are detected in soil gas samples are typically higher in shallow soil gas samples than in deeper soil gas samples).

The purpose of this Technical Memorandum (Memo) is to evaluate multimedia environmental data collected as part of the NPHE to identify inhalation COPCs that may be associated with a subsurface VI source versus other Non-VI sources (i.e., above-ground sources in ambient air and/or indoor air). It was not possible to differentiate between chemicals potentially resulting from poor waste disposal practices (dumping/burning of trash and hazardous waste) and other sources in this evaluation. Hence the focus of this Memo is to determine whether or not chemical concentrations found in soil gas are associated with subsurface VI sources that could contribute to VI in overlying buildings. This distinction is important so that the risks can be calculated appropriately and risk-management decisions can be made.

Uncontrolled waste-disposal practices (dumping and open-burning of uncollected trash and dumping of illegal waste) impact the environment both above-ground (ambient air/indoor air) and in the subsurface (soil and

groundwater). Other above-ground sources include typical urban contaminant sources such as nearby gasoline stations, automobile exhaust, dry cleaners, fuel storage tanks, diesel motors and generators, industrial facilities, agricultural practices, and landfills. Other subsurface VI sources include leaking underground storage tanks, leaking storage vessels, landfills, spills and releases associated with industrial, commercial and agricultural activities, and disposal of contaminated water through septic systems.

This Memo presents a review of soil gas and associated-media data that were collected in the nine study areas and uses a lines-of-evidence approach to identify COPCs that may be associated with a subsurface VI source versus above-ground ambient air sources.

It is important to note that none of the inhalation COPCs evaluated in this Memo were eliminated from the risk assessment. The results of this evaluation will be used to classify COPCs detected in soil gas into the following three groups so that the human health risks can be calculated appropriately.

- **Non-VI COPCs** – COPC(s) associated with ambient air and/or indoor air sources and not with a subsurface VI source. For these COPCs, human health risks for the inhalation pathway will be calculated based on ambient air concentrations.
- **Localized VI COPCs** – COPC(s) potentially associated with a subsurface VI source within a specific geographical area. Most COPCs fall into this category because subsurface VI is commonly associated with a localized release. This group also includes COPC(s) for which the determination was inconclusive. Risks for these COPCs will be calculated using either soil gas results or ambient air results depending on the determination at that location.
- **Global VI COPCs** – COPC(s) associated with a subsurface VI source at all locations. For these COPCs, there must be compelling evidence to indicate that subsurface VI is a site-wide issue. Risks for these COPCs will be calculated using soil gas results at all locations.

Note: The risks for these inhalation COPCs will be combined, as appropriate, with risks from other COPCs and exposure pathways in order to calculate cumulative human health risks at each sample location. Because the results of this Memo will be used to assist in making risk-management decisions, the tendency was to err toward identifying COPCs as being associated with a subsurface VI source rather than not.

1.2 BACKGROUND INFORMATION

1.2.1 Limitations

Summarized below are limitations that significantly impacted the NPHE and the development of this Memo:

- **Size of the Study Areas** – The total area of Campania covers approximately 5,250 square miles. The NPHE focused on the Naples Province of Campania where USN personnel work and live, which is approximately 395 square miles. The size of the study areas presents a challenge for developing sampling plans, interpreting the results, and developing conclusions about the area.
- **Jurisdiction for Sampling** – The USN does not have jurisdiction to collect samples in Italy other than at locations where U.S. personnel lease property. This fact presents a significant challenge/limitation for developing sampling plans because of the inability to gain access to some "desirable" locations to collect samples. The USN can only collect samples at locations where the tenant and landowner agree to grant access for sampling.

- **Lack of Site-Specific Geological/Hydrogeological Data** – At most environmental cleanup projects in the U.S. there is an abundance of historical geological and hydrogeological data available to develop sampling and analysis plans and also to assist in evaluating/interpreting the data. These data are also often supplemented by additional site-specific geological and hydrogeological information that is obtained during the environmental investigation. This is not the case in Italy. To date the USN has not been able to obtain reliable geological and/or hydrogeological data for the study areas. In addition, the USN cannot obtain site-specific data by collecting soil cores or installing monitoring wells on the economy because it does not have the authority to do so. This limitation impacts the VI investigation because depth to groundwater and geological characteristics are key inputs to assessing the potential for VI.
- **Lack of a Robust Paired (i.e., Co-located, Co-collected) Active Soil Gas and Ambient Air Data Set** – This Memo presents a comparison of soil gas and ambient air data (referred to as soil gas to ambient air ratios). A soil gas to ambient air ratio greater than one indicates that there is potentially a subsurface source of a COPC that could be a concern for VI. As this ratio increases, the indication of VI and associated subsurface contributing sources also increases. If the soil gas to ambient air ratio is less than or equal to one, this indicates that most likely the COPC is not associated with a subsurface VI source. For the NPHE, the vast majority of samples that were used to calculate the soil gas to ambient air ratios were not collected from the same location and were not collected at the same time (i.e., the soil gas and ambient air samples were not co-located or co-collected). The most significant limitations of this comparison are the temporal and spatial difference between the soil gas and ambient air samples. The ambient air samples used in the comparisons were obtained from U.S. Government-related sites that were typically located miles from the locations where the active soil gas samples were collected. These samples were also typically collected on different days than the active soil gas samples. These factors contribute uncertainty to the soil gas and ambient air comparisons. With greater distance and time between the samples collected, a higher degree of potential variability in concentrations is expected (assuming that there is no contribution from subsurface sources). However, in an effort to err on the side of being conservative, a soil gas to ambient air ratio of one or less was used as a line of evidence to identify a non-VI COPC.
- **Lack of Representative Background Ambient Air Concentrations for Naples, Italy** – Naples-specific background ambient air concentrations for the COPCs evaluated in this Memo were not available. This information would have been useful to provide context when evaluating the soil gas and ambient air data. In lieu of Naples-specific background ambient air data, chemical data from ambient air samples collected from six urban cities in the U.S. (San Diego, California, Los Angeles, California, Seattle, Washington, Houston, Texas, Midlothian, Texas, and Washington DC) from the 2007 USEPA Air Toxics Database [USEPA 2007]) were used to represent background concentrations from typical urban air. This limitation increases the uncertainty of this evaluation because there isn't any information to determine whether or not the ambient air data from the six U.S. cities are similar or different than the ambient air in Naples, Italy.
- **Single Sampling Event at Each Location** – In most cases, only one sample was collected from each medium (e.g., soil gas or tap water) at each location. In some cases this presents uncertainty because repeated or multiple samples would provide a more accurate representation of the concentrations to which people are exposed at each location. For example, it was assumed that the results of a single sampling event were representative of a 30-year exposure period. This limitation increased the uncertainty of the evaluation because it is likely that concentrations of the COPC in soil gas and tap water may change over time.

1.2.2 Sampling Events

For the NPHE, a phased approach was used to collect environmental data from within nine geographical study areas on the economy (Figure 1) (TetraTech, 2008). The first phase was conducted between June 9 and November 17, 2008 and was comprised of two components: 1) a month-long regional ambient air monitoring program at nine air sampling stations and 2) sampling of soil, passive soil gas, tap water (from both private well and municipal water sources) and irrigation wells, where available, from 130 residences (single-family homes and apartments) and 10 U.S. Government-related facilities¹. The results of Phase I sampling were assessed in a screening risk evaluation (SRE) to determine whether or not exposure to soil, indoor air, tap water, and ambient air posed an unacceptable risk to USN personnel, and whether or not additional assessment was necessary (PIONEER, 2009; TetraTech, 2008).

Based on the results of Phase I, Phase II was conducted to improve the geographic coverage of sampling locations in the nine study areas and to delineate clusters of residences that exceeded risk criteria (TetraTech, 2008). Approximately 200 residences have been sampled during Phase II (which is ongoing) and the ambient air monitoring program was continued for one full year. For Phase II, active (i.e., Summa Canister) sub-slab or near-slab soil gas samples were collected instead of the passive (i.e., Gore-Sorber®) sampling method that was used in Phase I. Soil sampling was discontinued midway through Phase II because results from Phase I samples indicated that soil had not been impacted to a degree that would pose a significant human health risk via incidental ingestion or dermal absorption.

As part of the Phase II sampling program, co-located ambient air and active soil gas samples were collected during the same sampling event (co-collected) at 27 locations to differentiate concentrations of COPCs in soil gas associated with subsurface sources from those associated with ambient air (i.e., outdoor air). Co-located groundwater and soil gas samples were also collected at select residential properties. Co-located samples were collected using the same sampling methodology as other Phase II samples (TetraTech, 2008).

1.2.3 Overview of the Data Sources Used in this Evaluation

The focus of this Memo is active soil gas data collected at 201 residences (locations) on the economy between November 2008 and July 2009. Data from the following media were included in this Memo:

- **Soil Gas:** Data from 204 active soil gas samples collected from 201 residences (locations) between November 2008 and July 2009 were included in this evaluation. Samples were collected from all nine study areas and included samples that were co-located and co-collected with ambient air and/or groundwater data. Only active soil gas samples collected from residential properties during Phase II were included in this evaluation. Active soil gas samples collected at U.S. Government-related facilities were not included because these facilities are being addressed separately.
- **Ambient Air:** Data from up to 392 ambient air samples were included in this evaluation. Samples were collected from nine ambient air monitoring stations located at U.S. Government-related facilities (air monitoring stations) (see Figure 1). Samples were collected approximately every six to nine days for one year (between June 2008 and July 2009) in order to determine representative air concentrations for each study area and also to capture random trash burning episodes, which typically peak in late spring and summer. Twenty-seven of the ambient air samples were co-located and co-collected with active soil gas samples at select residential properties.

¹ The 130 residences included the original seven pilot study residences.

- **Groundwater:** Phase I and Phase II groundwater data² from 88 residences were included in this evaluation. Tap water samples were documented as being from a private well or a public water system but only private well samples were used to represent subsurface groundwater because public water systems do not represent localized subsurface groundwater. Irrigation well samples were also collected and grouped with private tap water samples for the purpose of this evaluation. Twenty-eight of the 88 locations were co-located samples that were co-collected with active soil gas samples. All available groundwater data from Phase I and Phase II are included in this evaluation.

Data quality objectives and the sampling approaches for Phase I and Phase II are presented in the Project Specific Quality Assurance Project Plan (QAPP) Environmental Testing Support Assessment (TetraTech, 2008). Field sampling standard operating procedures (SOPs), sample collection methods, and analytical methods for the media evaluated in the Memo are summarized below (Note: Appendix E of the QAPP presents detailed field sampling SOPs and methods of collection for all media).

- **Ambient air samples** were collected from ambient air monitoring stations located five to six feet off the ground and upwind of other sampling devices. VOCs were collected using 6-liter SUMMA canisters over 24 hours and were analyzed using USEPA Method TO-15. SVOCs were collected using a polyurethane foam (PUF) sampler and were analyzed using USEPA Method TO-13A.
- **Ambient air samples** from select residential properties were co-collected with active soil gas samples from locations five to six feet off the ground upwind of the residence where soil gas samples were collected. They were collected using the same sampling protocol (6-liter SUMMA canisters over approximately two hours) as the soil gas samples and all chemicals (including SVOCs) were analyzed using USEPA Method TO-15.
- **Groundwater samples** were collected from tap water, private wells and irrigation wells. Tap water samples were collected from a faucet normally used for human use such as a kitchen or bathroom faucet. This evaluation only used tap water samples that originated from private wells. Samples were analyzed using USEPA Methods SW-846 8260 for VOCs and SW-846 8270 for SVOCs.
- **Active soil gas samples** were collected from residences by either a sub-slab or near-slab method. Samples were collected using 6-liter SUMMA canisters over a time period of 30 to 60 minutes. Sub-slab soil gas samples were collected from two to four inches beneath the floor slab of a garage or basement unless conditions prohibited access. Otherwise, near-slab soil gas samples were collected outside and within 10 feet of the building, at approximately five feet below ground surface (bgs). Active soil gas samples were analyzed for VOCs and select SVOCs using USEPA Method TO-15.

Naphthalene and acetaldehyde were among the chemicals tested for in soil gas and ambient air via USEPA Methods TO-13A and TO-15 for naphthalene and TO-11 and TO-15 for acetaldehyde. Inconsistencies in the results between the two methods (TO-13A and TO-15 for naphthalene and TO-11 and TO-15 for acetaldehyde) led to further research and it was determined that the active soil gas (and select ambient air) data for naphthalene and acetaldehyde analyzed by the USEPA Method TO-15 could not be sufficiently validated and should be rejected. Therefore, these COPCs were not included in this Memo. See Appendix F for a detailed discussion of the naphthalene and acetaldehyde data.

² Towards the end of Phase II, analyses of SVOCs (including hexachlorobutadiene) were discontinued because these COPCs were not shown to be of concern for groundwater. Three COPCs (1,3-butadiene, acrylonitrile and hexane) were not analyzed for groundwater because these COPCs are not included in USEPA's Methods SW-846 8260 (VOCs) and SW-846 8270 (SVOCs).

1.2.4 Statistical Summary of the of Data Used in this Evaluation

The environmental samples used in this evaluation were analyzed for various chemicals (noted in the QAPP), but only VOCs, SVOCs, and aldehydes were identified in soil gas samples at concentrations above their respective RSLs and these COPCs are the focus of this evaluation. Potential VI risks for each sample location were determined by calculating exceedance factors (EFs), which are the ratio of COPC concentrations to their RSLs³. Cancer EFs (CEFs) were calculated for COPCs that have been determined by the USEPA to be carcinogens. Noncarcinogenic (noncancer) EFs (NCEFs) were calculated for COPCs that have been determined by the USEPA to adversely affect human health via noncarcinogenic mechanisms.

Figure 2 presents the locations (to date) where active sub-slab and near-slab soil gas samples were collected in Phase II of the NPHE. About one-half of the samples were sub-slab samples and one half were near-slab samples. Twenty-two COPCs were identified as possibly contributing significantly to the cumulative risks at these residences because the COPC concentration in at least one soil gas sample exceeded its soil gas cancer or noncancer RSL (i.e., the CEF or NCEF was greater than one).

The analytical data for soil gas, ambient air, and groundwater data evaluated for each of the 22 COPCs in this Memo are summarized in Tables 1 through 3:

- **Table 1 – Soil Gas:** Summary statistics, cancer and noncancer RSLs, and the maximum CEF and NCEF for each of the 22 COPCs
- **Table 2 – Ambient Air:** Summary statistics, cancer and noncancer RSLs, and the maximum CEF and NCEF for each of the 22 COPCs
- **Table 3 – Groundwater:** Summary statistics, cancer and noncancer RSLs, and the maximum CEF and NCEF for each of the 22 COPCs

CEFs and NCEFs for each of the 22 COPCs in active soil gas and groundwater (where applicable) are presented on separate figures in Appendix A. This information is important to evaluate the spatial distribution of the CEFs and NCEFs.

1.3 DESCRIPTION OF THE LINE-OF-EVIDENCE APPROACH USED IN THIS EVALUATION

The line-of-evidence⁴ approach applied in this Memo incorporates a multi-faceted, multimedia evaluation of data from the nine study areas to determine whether or not the 22 COPCs with soil gas concentrations that exceeded their RSLs were chemicals that may be associated with VI (VI COPCs). This line-of-evidence approach was required because it is difficult to distinguish between chemicals in near-slab or sub-slab soil gas that are associated with VI from a subsurface VI source from those that are associated with a Non-VI (other) source (e.g., ambient air and/or indoor air). The results of this evaluation will be used to classify COPCs detected in soil gas into the following three groups so that the human health risks can be calculated appropriately.

- **Non-VI COPCs** – COPC(s) associated with ambient air and/or indoor air sources and not with a subsurface VI source. For these COPCs, human health risks for the inhalation pathway will be calculated based on ambient air concentrations.

³ The basis for the RSLs used in this Memo, is presented in the Phase I SRE (PTC, 2009) and the Preface to this Memo.

⁴ Multiple lines of evidence were evaluated systematically to make a determination (i.e., answer a question). Each line of evidence is evaluated separately using the data available for making a determination. The approach requires professional judgment for selecting and evaluating available information.

- **Localized VI COPCs** – COPC(s) potentially associated with a subsurface VI source within a specific geographical area. Most COPCs fall into this category because subsurface VI is commonly associated with a localized release. This group also includes COPCs for which the determination was inconclusive. Risks for these COPCs will be calculated based on soil gas concentrations at the specific locations where soil gas concentrations exceed the site-wide 95th percentile ambient air concentration⁵. At all other locations, the inhalation human health risks for these COPCs will be calculated based on ambient air concentrations.
- **Global VI COPCs** – COPCs associated with a subsurface VI source at all locations. For these COPCs, there must be compelling evidence to indicate that subsurface VI is a site-wide issue. For these COPCs, human health risks for the inhalation pathway will be calculated based on soil gas concentrations.

The lines of evidence that were used to classify the COPCs as Non-VI COPCs, Localized VI COPCs or Global VI COPCs are summarized below. Data and results used to support these lines of evidence and classifications are summarized on Table 4.

Primary Lines of Evidence – These are the key lines of evidence that were evaluated to classify the COPC as either associated with subsurface VI or not associated with VI.

1. **Was the COPC detected in groundwater? If so, was the Spatial Distribution of Groundwater Concentrations Consistent with Soil Gas Concentrations?** – For potential groundwater sources, the spatial distribution of COPC concentrations in soil gas should generally be consistent with the spatial distribution of groundwater concentrations (API, 2005). This relationship was evaluated by reviewing soil gas and groundwater figures (presented in Appendix A) as well as co-located/co-collected soil gas and groundwater data (for locations presented on Figure 3). For select COPCs, Figures 4a through 4f present co-located groundwater and soil gas sample locations where and indicate locations where the COPC was detected in both soil gas and groundwater.
 - **Decision Criteria:** If a COPC was detected in groundwater, and it was co-located with or proximate (within one mile) to a soil gas exceedance, then this line of evidence indicated that the COPC was potentially associated with a subsurface VI source. If the COPC was not detected in groundwater or was not co-located with or proximate to a soil gas exceedance, the conclusion that the COPC is not associated with a subsurface VI source is potentially true, but this conclusion is less certain. The absence of data from groundwater collected directly from a well, rather than from the tap, contributes to this uncertainty.

It is important to note that the evidence for groundwater as a potential VI source was supported by tetrachloroethene and trichloroethene data, which exhibited a strong spatial correlation between groundwater and active soil gas concentrations in Study Area 8 (see Figures 4a and 4b). Both tetrachloroethene and trichloroethene were frequently detected in groundwater and in active soil gas. These data provided very compelling evidence that groundwater was a source of these COPCs in soil gas in Study Area 8. It is also possible that there may be a source in soil in this area or hydraulically upgradient of the locations that were sampled in Study Area 8. The clear relationship between concentrations of tetrachloroethene in groundwater and active soil gas are contrasted by the lack of a relationship for 1,2-dichloropropane (Figure 4c), benzene (Figure 4d), chloroform (Figure 4e)⁶, and ethylbenzene (Figure 4f).

⁵ The 95th percentile concentrations for ambient air are based on the entire ambient air data set (collected over the 12+ months) and include non-detected values.

There is uncertainty associated with the groundwater data due to the lack of well-construction information, which is discussed in the Uncertainties section of the Memo (Section 1.5). The uncertainty analysis also includes an evaluation of the protectiveness of groundwater reporting limits, which are considered protective with respect to the VI pathway⁷.

2. **Soil Gas and Ambient Air Concentration Frequency Distribution Patterns** – Soil gas and ambient air data were plotted together on histograms in order to compare their distributions. These histograms are presented alphabetically, by COPC, in Appendix B. Histograms were created using all data⁸. The frequency distribution for soil gas and ambient air were compared for similarities or differences. A higher frequency of soil gas samples with concentrations in the upper range of the distribution (i.e., in the upper tail of the distribution) was a line of evidence for a localized subsurface VI source for that COPC. Conversely, a similar pattern and/or a higher frequency of ambient air samples in the upper range were evidence that the COPC concentrations in soil gas were likely associated with a Non-VI (ambient air) source. The 95th percentile concentration for ambient air was included for each COPC.

- **Decision Criteria:** If the concentration frequency distributions for a COPC were dissimilar and demonstrated higher soil gas concentrations (i.e., in the upper tail of the distribution), then this line of evidence indicated that the COPC was potentially associated with a VI source.

Note: The figures in Appendix B were annotated to identify similarities and differences observed on the frequency distributions (yellow annotation boxes) and to identify potential samples associated with localized subsurface VI (blue annotation boxes).

3. **Site-Wide Average Soil Gas to Average Ambient Air Ratios** – Average site-wide soil gas to average ambient air ratios were calculated for each COPC from all nine study areas. The average soil gas to ambient air ratio for each COPC is presented on Table 4.
 - **Decision Criteria:** If the site-wide average soil gas to average ambient air ratio exceeded one, then this line of evidence indicated that the COPC was potentially associated with a subsurface VI source. A Non-VI source was indicated if the average soil gas to average ambient air ratio was less than or equal to one⁹.
4. **Soil Gas to Ambient Air Ratios for Locations with Co-located, Co-collected Soil Gas and Ambient Air Data** – Co-located, co-collected data provided direct, location-specific evidence whether or not ambient air concentrations impact soil gas concentrations at that location. The relationship between soil gas and ambient air was presented as a ratio. Twenty-seven locations were sampled for both active soil gas and ambient air and the results for these samples are presented in Appendix C (Table C-1) and the locations are presented on Figure 3. The minimum, maximum, mean, and median soil gas to ambient air ratios are summarized in Table 4. The active soil gas to ambient air ratios for co-located, co-collected samples are presented on Figures 5a through 5d for benzene, chloroform, ethylbenzene and tetrachloroethene, respectively.

⁶ Of the remaining COPCs, chloroform shows the most locations with co-located detections in soil gas and groundwater. However, the correlation is limited to a much smaller area within Area 8 and Location 0548 (Area 6), which had an anomalously high concentration in soil gas.

⁷ The analytical limits of detection for COPCs were low enough to allow for a comparison between calculated indoor air concentrations derived from actual groundwater or soil gas data and the appropriate RSL.

⁸ All data, including J-flagged data and non-detected data were used to create the histograms. Intervals (bins) were selected based on the spread of the data. The frequency for each interval is based on the number of data points included in the bin that are less than or equal to the value selected for the interval and greater than the value selected for the lower interval.

⁹ Due to the inherent limitations of the data (including spatial and temporal variability) (see Section 1.5.3), a soil gas to ambient air ratio of one was selected to minimize uncertainties, but this ratio likely errs toward associating subsurface soil gas with VI sources rather than not.

- **Decision Criteria:** If the mean or median of the site-specific soil gas to site-specific ambient air concentration ratio exceeded one, then this line of evidence indicated that the COPC was potentially associated with a VI source¹⁰. A Non-VI source was indicated if the mean and median soil gas to ambient air ratio was less than or equal to one.

The number of primary lines of evidence indicating a Subsurface VI source and Non-VI source were tallied to determine whether a COPC should be classified as a VI COPC or Non-VI COPC. If the lines of evidence were equal, the COPC was assumed to be a VI COPC. Once determined to be a VI COPC, secondary lines of evidence were evaluated to categorize the VI COPC as Localized or Global. If the COPC was determined to be a Non-VI COPC, no further evaluation was performed.

Secondary Lines of Evidence – These lines of evidence were used to classify a VI COPC as a Localized VI COPC or a Global VI COPC.

1. **Geographical Distribution – Were VI COPC Concentrations Presented as Anomalies, Localized Clusters, or Widely-Distributed Clusters?** – Geographically-clustered VI COPC exceedances (i.e., clusters of at least three exceedances adjacent to one another) or anomalies (isolated exceedances) were considered an indicator of a potential Localized VI source area (i.e., possibly from a chemical release). A figure for each COPC detected in soil gas that exceeded its RSL is presented in alphabetical order in Appendix A. These figures present the geographical distribution of soil gas and groundwater exceedances.
 - **Decision Criteria:** Widely distributed clusters of VI COPC exceedances were evidence of a Global VI COPC. Localized clusters and/or anomalies were indicative of Localized VI COPCs.
2. **Frequency That Soil Gas Concentrations Exceeded their RSLs** – The frequency that soil gas concentrations exceeded the RSL provided an indication whether the COPC was potentially associated with subsurface VI sources throughout the study area or localized subsurface VI sources.
 - **Decision Criteria:** If the frequency of exceedance of the soil gas RSL was greater than 25 percent, then this line of evidence indicated that the COPC was potentially a Global VI COPC. If the frequency of exceedance of the soil gas RSL was less than or equal to 25 percent then this line of evidence indicated that the COPC was potentially a Localized VI COPC.

To be classified as a Global VI COPC, both secondary lines of evidence had to indicate a Global Subsurface VI Source. Otherwise, the COPC was determined to be a Localized VI COPC. The exception to the above criteria was for COPCs that were degradation products of a Global VI COPC. As discussed below, these were classified as Global VI COPCs by association.

¹⁰ Due to the inherent limitations of the data (including spatial and temporal variability) (see Section 1.5.3), a soil gas to ambient air ratio of one was selected to minimize uncertainties, but this ratio likely errs toward associating subsurface soil gas with VI sources rather than not.

Comments and Discussion – This information was evaluated to provide additional context and discussion specific to each COPC.

1. **Was the COPC a degradation product of a Global VI COPC?** – In some cases, a VI COPC met the requirements of a Localized VI COPC but was classified as Global VI COPCs because it was a degradation product of a Global VI COPC.
2. **Was the COPC considered a typical source of VI in the U.S.?** – The USEPA maintains a Vapor Intrusion Database that quantifies the number of VI investigations and samples where select COPCs have been detected in groundwater, soil gas, and sub-slab soil gas (USEPA 2008)¹¹. While not comprehensive, the VOCs tracked on this database have been documented at VI sites in the U.S. Other COPCs, considered “target VOCs” for VI investigations, or those typically associated with petroleum products, are also noted (New Jersey Department of Environmental Protection [NJDEP] 2005, API 2005). If the COPC was not tracked on the USEPA database or “short-listed” in NJDEP VI guidance, the COPC was not considered a typical VI COPC even though it may be included in some more comprehensive lists in VI Guidance (USEPA 2002).
3. **Was the Naples soil gas and/or ambient air concentration greater than the U.S. ambient air concentration for this COPC?** – For some COPCs, literature and available data support an ambient air source. The New York State Department of Health (NYSDOH) Soil Vapor Intrusion Guidance Appendix C: Volatile Organic Chemicals in Air – Summary of Background Databases (NYSDOH 2006) and the USEPA Air Toxics Database (USEPA, 2007)¹² were consulted for typical outdoor air concentrations.

1.4 RESULTS OF THE LINE-OF-EVIDENCE APPROACH

Each of the 22 COPCs was evaluated using primary and secondary lines of evidence presented in section 1.3 and the results were summarized, along with additional information, and tallied on a “Scorecard” for each COPC. Supporting information for each COPC is presented in Table 4. The decision criteria for the lines of evidence are presented in Table 5.

¹¹ The USEPA’s Vapor Intrusion Database can be downloaded from the Indoor Air Vapor Intrusion (IAVI) website at: <http://iavi.rti.org/>.

¹² Data from the USEPA Air Toxics Database were compiled and summarized in Table 3-3 of the Phase I SRE (PIONEER, 2009).

VI Lines-of-Evidence Summary for: 1,1,1,2-Tetrachloroethane

Background Information: 1,1,1,2-Tetrachloroethane is a chlorinated hydrocarbon. It is a colorless liquid with a sweet chloroform-like odor. It is used as a solvent and in the production of wood stains and varnishes. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

PRIMARY LINES OF EVIDENCE	DATA/RESULTS	DATA INDICATE A SUBSURFACE VI SOURCE	DATA INDICATE A NON-VI SOURCE
1. COPC Detected in Groundwater/Spatial Distribution of Groundwater is Consistent with Soil Gas? ²	No / No (Detected in 0 of 88 groundwater samples)	no	Yes
2. Soil Gas & Ambient Air Concentration Frequency Distribution Patterns.	Soil gas and ambient air distributions are similar a indicate higher frequency of soil gas concentrations in upper tail of distribution. See Figure B – 1	Yes	no
3. Site-Wide Average Soil Gas to Average Ambient Air Ratio Greater than 1?	10	Yes	no
4. Mean or Median Soil Gas to Ambient Air Ratio for Locations with Co-located, Co-collected Soil Gas and Ambient Air Data Greater than 1?	Not detected in co-collected, co-located soil gas or ambient air samples ³ .	no	no
<i>Number of Primary Lines of Evidence Supporting Classification:</i>		<i>2</i>	<i>1</i>
Conclusion⁴:	Data indicate that this COPC is potentially associated with a subsurface VI source.		
SECONDARY LINES OF EVIDENCE (FOR COPCs ASSOCIATED WITH A SUBSURFACE VI SOURCE)	DATA/RESULTS	DATA INDICATE A GLOBAL VI COPC	DATA INDICATE A LOCALIZED VI COPC
1. Geographical Distribution	Anomalies See Figure A – 1	no	Yes
2. Frequency that Soil Gas Concentrations Exceed the RSL	1.5% – 3 of 201 locations.	no	Yes
Comments/Discussion:	<ul style="list-style-type: none"> ▪ Maximum CEF is 7.6 ▪ This COPC is not considered a common VI COPC in the U.S. ▪ No U.S. background ambient air values are available for this COPC. ▪ See Table 4, Appendix A, and Appendix B for detailed information. 		
Conclusion⁵:	Localized VI COPC		

Notes:

-- = No data

CEF = Cancer Exceedance Factor

¹No data are available regarding the use of this chemical in Italy.

²The presence or absence of a COPC in groundwater is a line of evidence used to determine whether elevated concentrations in soil gas were associated with subsurface VI. Although the presence of a chemical in tap water or irrigation well water is a clear line of evidence to support the potential for a subsurface VI source, the converse relationship (associating the absence of a COPC in tap water or irrigation well water with the absence of a subsurface VI source) is less certain.

³Soil gas and ambient air concentrations were non-detect in all co-located, co-collected samples, indicating that there was not a VI source and there was not an ambient air source at these locations.

⁴If the number of Primary Lines of Evidence supporting a Subsurface VI Source was greater than or equal to the number of Primary Lines of Evidence Supporting a Non-VI Source, then the COPC was assumed to be associated with a Subsurface VI Source.

⁵VI COPCs were assumed to be Localized VI COPCs unless there was compelling evidence to indicate that the VI COPC was a Global VI COPC. Both Secondary Lines of Evidence and additional information were used to make this determination.

VI Lines-of-Evidence Summary for: 1,1,2,2-Tetrachloroethane

Background Information: 1,1,2,2-Tetrachloroethane is a manufactured, colorless, dense liquid that does not burn easily. It is volatile and has a sweet odor. In the past, it was used in large amounts to produce other chemicals, as an industrial solvent to clean and degrease metals, and as an ingredient in paints and pesticides. Commercial production of 1,1,2,2-tetrachloroethane for these uses has stopped in the United States. It presently is used only as a chemical intermediate in the production of other chemicals. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

PRIMARY LINES OF EVIDENCE	DATA/RESULTS	DATA INDICATE A SUBSURFACE VI SOURCE	DATA INDICATE A NON-VI SOURCE
1. COPC Detected in Groundwater/Spatial Distribution of Groundwater is Consistent with Soil Gas? ²	No / No Detected in 0 of 88 groundwater samples	no	Yes
2. Soil Gas & Ambient Air Concentration Frequency Distribution Patterns.	Soil gas and ambient air distributions are similar. See Figure B – 2	no	Yes
3. Site-Wide Average Soil Gas to Average Ambient Air Ratio Greater than 1?	1.1	Yes	no
4. Mean or Median Soil Gas to Ambient Air Ratio for Locations with Co-located, Co-collected Soil Gas and Ambient Air Data Greater than 1?	Mean = 1.0 and Median = 1.1	Yes	no

Conclusion⁴:		Localized VI COPC	

Notes:

-- = No data

CEF = Cancer Exceedance Factor

¹No data are available regarding the use of this chemical in Italy.

²The presence or absence of a COPC in groundwater is a line of evidence used to determine whether elevated concentrations in soil gas were associated with subsurface VI. Although the presence of a chemical in tap water or irrigation well water is a clear line of evidence to support the potential for a subsurface VI source, the converse relationship (associating the absence of a COPC in tap water or irrigation well water with the absence of a subsurface VI source) is less certain.

³If the number of Primary Lines of Evidence supporting a Subsurface VI Source was greater than or equal to the number of Primary Lines of Evidence Supporting a Non-VI Source, then the COPC was assumed to be associated with a Subsurface VI Source.

⁴VI COPCs were assumed to be Localized VI COPCs unless there was compelling evidence to indicate that the VI COPC was a Global VI COPC. Both Secondary Lines of Evidence and additional information were used to make this determination.

VI Lines-of-Evidence Summary for: 1,2-Dibromo-3-Chloropropane

Background Information: 1,2-Dibromo-3-chloropropane is a manufactured chemical and is not found naturally in the environment. It is a colorless liquid with a sharp smell. It can be tasted in water at very low concentrations. Some industries use it to make another chemical that is used to make materials that resist burning. Large amounts of 1,2-dibromo-3-chloropropane were used in the past on certain farms to kill pests that harmed crops. Farmers in all states other than Hawaii stopped using this chemical in 1979. Hawaii stopped using it in 1985. We do not know exactly how much of it is currently made or used by industry, but it is probably a small amount. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

VI Lines-of-Evidence Summary for: 1,2-Dibromoethane

Background information: 1,2-Dibromoethane is a manufactured chemical. It also occurs naturally in small amounts in the ocean where it is formed, probably by algae and kelp. It is a colorless liquid with a mild, sweet odor. Other names for 1,2-dibromoethane are ethylene dibromide, EDB, and glycol bromide. Trade names include Bromofume and Dowfume. 1,2-Dibromoethane has been used as a pesticide in soil, and on citrus, vegetable, and grain crops. Most of these uses have been stopped by the Environmental Protection Agency (EPA) since 1984. Another major use was as an additive in leaded gasoline; however, since leaded gasoline is now banned, it is no longer used for this purpose. Uses today include treatment of logs for termites and beetles, control of moths in beehives, and as a preparation for dyes and waxes. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

VI Lines-of-Evidence Summary for: 1,2-Dichloroethane

Background Information: 1,2-Dichloroethane, also called ethylene dichloride, is a manufactured chemical that is not found naturally in the environment. It is a clear liquid and has a pleasant smell and sweet taste. The most common use of 1,2-dichloroethane is in the production of vinyl chloride which is used to make a variety of plastic and vinyl products including polyvinyl chloride (PVC) pipes, furniture and automobile upholstery, wall coverings, housewares, and automobile parts. It is also used as a solvent and is added to leaded gasoline to remove lead. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

VI Lines-of-Evidence Summary for: 1,2-Dichloropropane

Background Information: 1,2-Dichloropropane is a colorless, flammable liquid with a chloroform-like odor. It is moderately soluble in water and readily evaporates into air. It does not occur naturally in the environment. 1,2-Dichloropropane production in the United States has declined over the past 20 years. It was used in the past as a soil fumigant, chemical intermediate, and industrial solvent and was found in paint strippers, varnishes, and furniture finish removers. Most of these uses were discontinued. Today, almost all of the 1,2-dichloropropane is used as a chemical intermediate to make perchloroethylene and several other related chlorinated chemicals. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

VI Lines-of-Evidence Summary for: 1,4-Dichlorobenzene

Background Information: There are three dichlorobenzene isomers- 1,2-dichlorobenzene, 1,3-dichlorobenzene, and 1,4-dichlorobenzene. Dichlorobenzenes do not occur naturally. 1,2-Dichlorobenzene is a colorless to pale yellow liquid used to make herbicides. 1,3- Dichlorobenzene is a colorless liquid used to make herbicides, insecticides, medicine, and dyes. 1,4-Dichlorobenzene, the most important of the three chemicals, is a colorless to white solid with a strong, pungent odor. When exposed to air, it slowly changes from a solid to a vapor. Most people can smell 1,4- dichlorobenzene in the air at very low levels. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

³Soil gas and ambient air concentrations were non-detect in all co-located, co-collected samples, indicating that there was not a VI source and there was not an ambient air source at these locations.

⁴If the number of Primary Lines of Evidence supporting a Subsurface VI Source was greater than or equal to the number of Primary Lines of Evidence Supporting a Non-VI Source, then the COPC was assumed to be associated with a Subsurface VI Source.

⁵VI COPCs were assumed to be Localized VI COPCs unless there was compelling evidence to indicate that the VI COPC was a Global VI COPC. Both Secondary Lines of Evidence and additional information were used to make this determination.

VI Lines-of-Evidence Summary for: Benzene

Background Information: Benzene is a colorless liquid with a sweet odor. It evaporates into the air very quickly and dissolves slightly in water. It is highly flammable and is formed from both natural processes and human activities. Benzene is widely used in the United States; it ranks in the top 20 chemicals for production volume. Some industries use benzene to make other chemicals which are used to make plastics, resins, and nylon and other synthetic fibers. Benzene is also used to make some types of rubbers, lubricants, dyes, detergents, drugs, and pesticides. Natural sources of benzene include emissions from volcanoes and forest fires. Benzene is also a natural part of crude oil, gasoline, and cigarette smoke. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

PRIMARY LINES OF EVIDENCE	DATA/RESULTS	DATA INDICATE A SUBSURFACE VI SOURCE	DATA INDICATE A NON-VI SOURCE
1. COPC Detected in Groundwater/Spatial Distribution of Groundwater is Consistent with Soil Gas? ²	No / No Detected in 0 of 88 groundwater samples	no	Yes
2. Soil Gas & Ambient Air Concentration Frequency Distribution Patterns.	Soil gas and ambient air distributions are not similar with higher frequency of soil gas in the upper tail of the distribution. See Figure B – 11	Yes	no
3. Site-Wide Average Soil Gas to Average Ambient Air Ratio Greater than 1?	2.6	Yes	no
4. Mean or Median Soil Gas to Ambient Air Ratio for Locations with Co-located, Co-collected Soil Gas and Ambient Air Data Greater than 1?	Mean = 12 and Median = 2.5 See Figure 5a	Yes	no
<i>Number of Primary Lines of Evidence Supporting Classification:</i>		<i>3</i>	<i>1</i>
Conclusion³:	Data indicate that this COPC is potentially associated with a subsurface VI source.		
SECONDARY LINES OF EVIDENCE (FOR COPCs ASSOCIATED WITH A VI SOURCE)	DATA/RESULTS	DATA INDICATE A GLOBAL VI COPC	DATA INDICATE A LOCALIZED VI COPC
1. Geographical Distribution	Localized clusters and anomalies See Figures A-19	no	Yes
2. Frequency that Soil Gas Concentrations Exceeded the RSL	25% – 50 of 201 locations	no	Yes
Comments/Discussion:	<ul style="list-style-type: none"> ▪ Maximum CEF is 145 ▪ This COPC is considered a common VI COPC in the U.S and is tracked on USEPA's VI Database (2008) and listed in NJDEP's VI Guidance (2007). ▪ Maximum soil gas (451 ug/m³) and maximum ambient air (454 ug/m³) concentrations measured in Naples are greater than maximum ambient air concentrations in the U.S (17 ug/m³). ▪ See Table 4, Appendix A, and Appendix B for detailed information. 		
Conclusion⁴:	Localized VI COPC		

Notes:

-- = No data

CEF = Cancer Exceedance Factor

¹No data are available regarding the use of this chemical in Italy.

²The presence or absence of a COPC in groundwater is a line of evidence used to determine whether elevated concentrations in soil gas were associated with subsurface VI. Although the presence of a chemical in tap water or irrigation well water is a clear line of evidence to support the potential for a subsurface VI source, the converse relationship (associating the absence of a COPC in tap water or irrigation well water with the absence of a subsurface VI source) is less certain.

³If the number of Primary Lines of Evidence supporting a Subsurface VI Source was greater than or equal to the number of Primary Lines of Evidence Supporting a Non-VI Source, then the COPC was assumed to be associated with a Subsurface VI Source.

⁴VI COPCs were assumed to be Localized VI COPCs unless there was compelling evidence to indicate that the VI COPC was a Global VI COPC. Both Secondary Lines of Evidence and additional information were used to make this determination.

VI Lines-of-Evidence Summary for: Bromoform

Background Information: Bromoform and dibromochloromethane are colorless to yellow, heavy, nonflammable, liquids with a sweet odor. Small amounts are formed naturally by plants in the ocean. They are somewhat soluble in water and readily evaporate into the air. Most of the bromoform and dibromochloromethane that enters the environment is formed as byproducts when chlorine is added to drinking water to kill bacteria. Only small quantities of bromoform and dibromochloromethane currently are produced in the United States. These chemicals were used in the past as solvents and flame retardants, or to make other chemicals, but now they are used mainly as laboratory reagents. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

PRIMARY LINES OF EVIDENCE	DATA/RESULTS	DATA INDICATE A SUBSURFACE VI SOURCE	DATA INDICATE A NON-VI SOURCE
1. COPC Detected in Groundwater/Spatial Distribution of Groundwater is Consistent with Soil Gas? ²	Yes / Yes Detected in 12 of 88 groundwater samples	YES	no
2. Soil Gas & Ambient Air Concentration Frequency Distribution Patterns.	Soil gas and ambient air distributions are similar but indicate higher frequency of soil gas concentrations in upper tail of distribution See Figure B – 12	Yes	no
3. Site-Wide Average Soil Gas to Average Ambient Air Ratio Greater than 1?	210.4	Yes	no
4. Mean or Median Soil Gas to Ambient Air Ratio for Locations with Co-located, Co-collected Soil Gas and Ambient Air Data Greater than 1?	Not detected in co-collected, co-located soil gas or ambient air samples ³	no	no
<i>Number of Primary Lines of Evidence Supporting Classification:</i>		<i>3</i>	<i>0</i>
Conclusion⁴:	Data indicate that this COPC is potentially associated with a subsurface VI source.		
SECONDARY LINES OF EVIDENCE (FOR COPCs ASSOCIATED WITH A VI SOURCE)	DATA/RESULTS	DATA INDICATE A GLOBAL VI COPC	DATA INDICATE A LOCALIZED VI COPC
1. Geographical Distribution	Anomalies See Figure A – 21	no	Yes
2. Frequency that Soil Gas Concentrations Exceeded the RSL	<1% – 1 of 201 locations	no	Yes
Comments/Discussion:	<ul style="list-style-type: none"> ▪ Maximum CEF is 6.6 ▪ This COPC is listed in NJDEP's VI Guidance (2007) but is not tracked in USEPA's VI Database (2008). ▪ No U.S. background ambient air values are available for this COPC. ▪ See Table 4, Appendix A, and Appendix B for detailed information. 		
Conclusion⁵:	Localized VI COPC		

Notes:

-- = No data

CEF = Cancer Exceedance Factor

¹No data are available regarding the use of this chemical in Italy.

VI Lines-of-Evidence Summary for: Carbon Tetrachloride

Background Information: Carbon tetrachloride is a manufactured chemical that does not occur naturally. It is a clear liquid with a sweet smell that can be detected at low levels. It is also called carbon chloride, methane tetrachloride, perchloromethane, tetrachloroethane, or benziform. Carbon tetrachloride is most often found in the air as a colorless gas. It is not flammable and does not dissolve in water very easily. It was used in the production of refrigeration fluid and propellants for aerosol cans, as a pesticide, as a cleaning fluid and degreasing agent, in fire extinguishers, and in spot removers. Because of its harmful effects, these uses are now banned and it is only used in some industrial applications. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

⁴VI COPCs were assumed to be Localized VI COPCs unless there was compelling evidence to indicate that the VI COPC was a Global VI COPC. Both Secondary Lines of Evidence and additional information were used to make this determination.

VI Lines-of-Evidence Summary for: Chloroform

Background Information: Chloroform is a colorless liquid with a pleasant, nonirritating odor and a slightly sweet taste. It will burn only when it reaches very high temperatures. In the past, chloroform was used as an inhaled anesthetic during surgery, but it isn't used that way today. Today, chloroform is used to make other chemicals and can also be formed in small amounts when chlorine is added to water. Other names for chloroform are trichloromethane and methyl trichloride. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

PRIMARY LINES OF EVIDENCE	DATA/RESULTS	DATA INDICATE A SUBSURFACE VI SOURCE	DATA INDICATE A NON-VI SOURCE

VI Lines-of-Evidence Summary for: Hexane

Background Information: n-Hexane is a chemical made from crude oil. Pure n-hexane is a colorless liquid with a slightly disagreeable odor. It is highly flammable, and its vapors can be explosive. Pure n-hexane is used in laboratories. Most of the n-hexane used in industry is mixed with similar chemicals called solvents. The major use for solvents containing n-hexane is to extract vegetable oils from crops such as soybeans. These solvents are also used as cleaning agents in the printing, textile, furniture, and shoemaking industries. Certain kinds of special glues used in the roofing and shoe and leather industries also contain n-hexane. Several consumer products contain n-hexane, such as gasoline, quick-drying glues used in various hobbies, and rubber cement. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

VI Lines-of-Evidence Summary for: Methyl Tert-Butyl Ether

Background Information: Methyl tert-butyl ether (MTBE) is a flammable liquid with a distinctive, disagreeable odor. It is made from blending chemicals such as isobutylene and methanol, and has been used since the 1980s as an additive for unleaded gasolines to achieve more efficient burning. MTBE is also used to dissolve gallstones. Patients treated in this way have MTBE delivered directly to their gall bladders through special tubes that are surgically inserted. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

VI Lines-of-Evidence Summary for: Tetrachloroethene

Background Information: Tetrachloroethene is a manufactured chemical that is widely used for dry cleaning of fabrics and for metal-degreasing. It is also used to make other chemicals and is used in some consumer products. Other names for tetrachloroethene include perchloroethylene, PCE, and tetrachloroethene. It is a nonflammable liquid at room temperature. It evaporates easily into the air and has a sharp, sweet odor. Most people can smell tetrachloroethene when it is present in the air at a level of 1 part tetrachloroethene per million parts of air (1 ppm) or more, although some can smell it at even lower levels. PRIMARY LINES OF EVIDENCE	DATA/RESULTS	DATA INDICATE A SUBSURFACE VI SOURCE	DATA INDICATE A NON-VI SOURCE
1. COPC Detected in Groundwater/Spatial Distribution of Groundwater is Consistent with Soil Gas? ²	Yes / Yes Detected in 64 of 88 groundwater samples See Figures A-36 & A-37 (from Appendix A) for all groundwater and soil gas sample locations and Figure 4a for co-located groundwater and soil gas samples only.	Yes	no
2. Soil Gas & Ambient Air Concentration Frequency Distribution Patterns.	Soil gas and ambient air concentration distribution patterns are not similar and indicate higher frequencies of elevated soil gas concentrations in the upper tail of the distribution. See Figure B – 20	Yes	no
3. Site-Wide Average Soil Gas to Average Ambient Air Ratio Greater than 1?	23	Yes	no
4. Mean or Median Soil Gas to Ambient Air Ratio for Locations with Co-located, Co-collected Soil Gas and Ambient Air Data Greater than 1?	Mean = 61 and Median = 18 See Figure 5d	Yes	no
<i>Number of Primary Lines of Evidence Supporting Classification:</i>		<i>4</i>	<i>0</i>
Conclusion³:	Data indicate that this COPC is potentially associated with a subsurface VI source.		
SECONDARY LINES OF EVIDENCE (FOR COPCs ASSOCIATED WITH A VI SOURCE)	DATA/RESULTS	DATA INDICATE A GLOBAL VI COPC	DATA INDICATE A LOCALIZED VI COPC
1. Geographical Distribution	Clustered and widely distributed See Figure A – 36	Yes	no
2. Frequency that Soil Gas Concentrations Exceeded the RSL	65% – 131 of 201 locations	Yes	no
Comments/Discussion:	<ul style="list-style-type: none"> ▪ Maximum CEF is 798 ▪ This COPC is considered a common VI COPC in the U.S and is tracked on USEPA's VI Database (2008) and listed in NJDEP's VI Guidance (2007). ▪ Maximum soil gas (3,270 ug/m³) and maximum ambient air (56.7 ug/m³) concentrations measured in Naples are greater than maximum ambient air concentrations in the U.S (20 ug/m³). ▪ See Table 4, Appendix A, and Appendix B for detailed information. 		
Conclusion⁴:	Global VI COPC		

Notes:

-- = No data

CEF = Cancer Exceedance Factor

¹No data are available regarding the use of this chemical in Italy.

²The presence or absence of a COPC in groundwater is a line of evidence used to determine whether elevated concentrations in soil gas were associated with subsurface VI. Although the presence of a chemical in tap water or irrigation well water is a clear line of evidence to support the potential for a subsurface VI source, the converse relationship (associating the absence of a COPC in tap water or irrigation well water with the absence of a subsurface VI source) is less certain.

³If the number of Primary Lines of Evidence supporting a Subsurface VI Source was greater than or equal to the number of Primary Lines of Evidence Supporting a Non-VI Source, then the COPC was assumed to be associated with a Subsurface VI Source.

⁴VI COPCs were assumed to be Localized VI COPCs unless there was compelling evidence to indicate that the VI COPC was a Global VI COPC. Both Secondary Lines of Evidence and additional information were used to make this determination.

VI Lines-of-Evidence Summary for: Trichloroethene

Background Information: Trichloroethene (TCE) is a nonflammable, colorless liquid with a somewhat sweet odor and a sweet, burning taste. It is used mainly as a solvent to remove grease from metal parts, but it is also an ingredient in adhesives, paint removers, typewriter correction fluids, and spot removers. Trichloroethene is not thought to occur naturally in the environment. However, it has been found in underground water sources and many surface waters as a result of the manufacture, use, and disposal of the chemical. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

⁵Because trichloroethene is a degradation product of tetrachloroethene (which is classified as a Global VI COPC), trichloroethene is classified as a Global VI COPC

VI Lines-of-Evidence Summary for: Vinyl Chloride

Background Information: Vinyl chloride is a colorless gas. It burns easily and it is not stable at high temperatures. It has a mild, sweet odor. It is a manufactured substance that does not occur naturally. It can be formed when other substances such as trichloroethane, trichloroethene, and tetrachloroethene are broken down. Vinyl chloride is used to make polyvinyl chloride (PVC). PVC is used to make a variety of plastic products, including pipes, wire and cable coatings, and packaging materials. Vinyl chloride is also known as chloroethene, chloroethylene, and ethylene monochloride. Source: <http://www.atsdr.cdc.gov/toxfaq.html>.¹

Conclusion⁵:	Global VI COPC⁶		

Notes:

-- = No data

CEF = Cancer Exceedance Factor

¹No data are available regarding the use of this chemical in Italy.

²The presence or absence of a COPC in groundwater is a line of evidence used to determine whether elevated concentrations in soil gas were associated with subsurface VI. Although the presence of a chemical in tap water or irrigation well water is a clear line of evidence to support the potential for a subsurface VI source, the converse relationship (associating the absence of a COPC in tap water or irrigation well water with the absence of a subsurface VI source) is less certain.

³Soil gas and ambient air concentrations were non-detect in all co-located, co-collected samples, indicating that there was not a VI source and there was not an ambient air source at these locations.

⁴If the number of Primary Lines of Evidence supporting a VI Source is greater than or equal to the number of Primary Lines of Evidence Supporting a Non-VI Source, then the COPC is assumed to be associated with a VI Source.

⁵VI COPCs were assumed to be Localized VI COPCs unless there was compelling evidence to indicate that the VI COPC was a Global VI COPC. Both Secondary Lines of Evidence and additional information were used to make this determination.

⁶Because vinyl chloride is a degradation product of tetrachloroethene (which is classified as a Global VI COPC), vinyl chloride is classified as a Global VI COPC.

1.5 UNCERTAINTIES

There are many confounding factors that must be considered when identifying COPCs that may be potentially associated with VI to indoor air, including the chemical/physical properties of the COPCs, soil and groundwater characteristics, ambient air conditions, and the construction and ventilation features of the buildings. The results, analyses, conclusions, and recommendations presented in this Memo depend on the quality and quantity of the data and should be considered in the context of the key uncertainties associated with the collection, analyses, and interpretation of groundwater, soil gas, and ambient air data that are discussed in the following sections.

1.5.1 Groundwater

At most VI sites, COPCs in groundwater are the primary source of VI. Therefore, groundwater quality provides a key line of evidence to identify VI COPCs because, when groundwater is a source of VI, the spatial distribution of COPC concentrations in soil gas should be generally consistent with the spatial distribution of groundwater concentrations (API, 2005). Key uncertainties associated with the groundwater results used in this evaluation are discussed in the following sections.

1.5.1.1 Collection of Groundwater Samples

The Navy was only able to obtain information regarding groundwater quality at locations (residences) that obtain their tap water from private wells because the Navy was not authorized to install groundwater monitoring wells as part of the NPHE. As a result, groundwater results were not available in most study areas to compare with soil gas results. For example, all of the locations sampled in Study Areas 2, 3 and 4 obtain their tap water from public water systems, so no groundwater results were available from these areas. Only one location in Study Area 6 (Location 0548) obtains their tap water from a private well. The lack of groundwater data in these Study Areas is a significant data gap that increases the uncertainty in identifying COPCs associated with VI.

Groundwater samples were collected by sampling the kitchen or bathroom tap water at locations connected to private wells (not public water systems) or, if tap water was unavailable, samples were collected from irrigation wells. No information was available regarding the construction of the private wells (e.g., depth to groundwater, screen interval, screen size, casing diameter, lithology, et cetera). This is a significant uncertainty because the screen intervals for private wells were assumed to be shallow, which maximizes the potential for VI from a source in groundwater. This assumption may overestimate or underestimate the potential for VI from groundwater.

The presence or absence of a COPC in groundwater one a line of evidence used to determine whether elevated concentrations in soil gas were associated with subsurface VI or not. Although the presence of a chemical in tap water or irrigation well water is a clear line of evidence to support the potential for subsurface VI, the converse relationship (associating the absence of a COPC in groundwater with the absence of a subsurface VI source) is less certain. Many domestic water systems have a holding tank where groundwater is initially pumped. The water sits in the holding tank until needed by members of the household. Many of these tanks have elevated levels of bacteria in them. Aerobically-biodegradable chemicals such as benzene and ethylbenzene, if present in groundwater, could degrade to non-detected levels while sitting in the holding tank. This could explain why these chemicals, which are ubiquitous in water-table groundwater in the U.S., were not detected in any tap water samples collected in Naples. Tetrachloroethene and trichloroethene, in contrast, are biodegradable, but conditions need to be correct (anaerobic conditions and presence of a carbon substrate) for these chemicals to be degraded. In other words, tetrachloroethene and trichloroethene are not likely to biodegrade in the aerobic conditions likely present in the holding tanks. However, this does not explain why other chemicals, detected at a high frequency in soil gas but not

in tap water (e.g., 1,2-dichloropropane, acrolein, hexachlorobutadiene) would not persist in tap water if they were associated with a VI subsurface source, since they would also not be expected to degrade as readily.

1.5.1.2 Analysis and Interpretation of Groundwater Samples

Not all of the COPCs identified in soil gas were analyzed in groundwater samples. The lack of groundwater data created an uncertainty in determining whether or not impacted groundwater was a source of subsurface VI for these COPCs.

- Hexachlorobutadiene was only analyzed in 61 of 83 groundwater samples. Therefore, it was not possible to evaluate groundwater data as a line of evidence for this COPC at some locations (including locations with co-located, co-collected soil gas samples) that obtain their tap water from a private well (i.e., groundwater).
- Three soil gas COPCs (acrylonitrile, 1,3 butadiene, and hexane) were not analyzed for in groundwater samples because they are not included in USEPA Methods SW-846 8260 (VOCs) and SW-846 8270 (SVOCs). Therefore, it was not possible to evaluate groundwater data as a line of evidence for these COPCs.

Note: Groundwater reporting limits are not a significant uncertainty with regard to evaluating the VI pathway. This is demonstrated by using Henry's Law to back-calculate the groundwater concentration that would be expected to result in the minimum soil gas concentration observed for each COPC. As shown on Table 6, for all COPCs, the minimum and maximum groundwater reporting limits are protective of the VI pathway (i.e., the groundwater reporting limits are lower than groundwater concentrations predicted using soil gas concentrations and Henry's Law), thus indicating that the groundwater reporting limits are protective of VI to indoor air. Therefore, locations with exceedances in soil gas should correlate with detected concentrations in the groundwater if there is a VI source.

1.5.2 Soil Gas

Key uncertainties associated with soil gas are discussed in the following sections.

1.5.2.1 Collection of Active Soil Gas Samples

The Navy could only obtain soil gas samples from locations in the greater Naples area of the Campania Region that were occupied by U.S. personnel, and where access was granted by the landlord/property owner to collect the samples. Therefore, soil gas samples were not evenly distributed throughout the nine Study Areas. The majority of soil gas samples collected were from Study Areas 1, 2, 7 and 8 and only a small percentage were collected in the remaining areas.

The nine study areas comprise approximately 395 square miles. Spatial variability in sub-slab concentrations can span orders of magnitude (Folkes et al., 2009). Because the soil gas samples evaluated in this Memo were collected from locations throughout the study areas, spatial variability adds to the uncertainty. Variations in subsurface conditions, sub-slab conditions, building size, and operating pressures within each building, in addition to natural fluctuations in barometric pressures over time increased the uncertainty and subsequently resulted in under-estimating or over-estimating concentrations associated with VI. In most cases, only one soil gas sample was collected for each structure, which is insufficient to represent conditions at some buildings.

At most locations, the soil gas evaluation was based on one sampling event and these results were compared to an average of ambient air data that were collected over a period of one year. Studies have shown a significant variability between soil gas samples collected over a longer-term (months) period (McHugh and Nickels, 2007).

Soil gas samples were collected either directly beneath the floor of the residence or garage (i.e., two to four inches below the bottom of the concrete slab) (sub-slab) or within 10 feet of the residence at a depth of approximately five feet below ground surface (near-slab). Almost one-half of the soil gas samples (49 percent) were near-slab samples. Studies conducted by the USEPA and various state agencies have raised concerns as to the appropriateness of near-slab soil gas data in the investigation of the VI pathway (NJDEP, 2005). NJDEP points to concerns with false negatives as a function of soil type, soil moisture, or impermeable layers that do not represent conditions beneath the slab (NJDEP, 2005).

A comparison of near slab and sub-slab data for several COPCs (benzene, ethylbenzene, chloroform, tetrachloroethene, 1,2-dichloropropane, carbon tetrachloride, trichloroethene) from the Naples region revealed that there was a higher frequency of elevated soil gas to ambient air ratios for sub-slab versus near-slab samples. Sixty-one (61) percent of the near-slab soil gas samples had soil gas to ambient air ratios at or below one in comparison to 38 percent of the sub-slab soil gas samples. This could indicate a false negative bias for the near-slab samples or it could represent more influence from ambient air concentrations.

Oxygen transport from the atmosphere to soil gas beneath a slab-on-grade has been studied in regards to biodegradation of petroleum-contaminated soil (Lundegard et. al., 2008). These studies have shown a rapid replenishment of oxygen following nitrogen flooding (to remove oxygen from subsurface soil). This is attributed to both vertical exchange across the concrete slab and advective transport immediately below the concrete slab. A similar recovery was noted for near-slab soil gas. The broad scope and multiple variables associated with the Naples soil gas sampling program are too substantial to fully understand the factors contributing to sub-slab versus near-slab soil gas concentrations and the information necessary to further evaluate these factors (e.g., lithology, building type, and hydrogeology) have not been readily available. However, the data indicate that additional field information should be collected to the extent possible during future sampling events.

For these reasons, more than one line of evidence was used to determine whether or not a VI source was possible at each soil gas location.

1.5.2.2 Analysis and Interpretation of Soil Gas Samples

Inhalation risks associated with VI of chemicals in soil gas to indoor air can vary by orders of magnitude depending on the degree of the attenuation that occurs between soil gas and indoor air. Subsurface conditions and building characteristics vary across the nine study areas, and because building access was not always achievable, some soil gas samples were collected sub-slab and some were collected outside of the building (near-slab). However, all soil gas sample concentrations, regardless of how they were collected, are compared to RSLs that were calculated using the USEPA's default VAF (α) of 0.1 (normally used for sub-slab soil gas), which is also the VAF specified in the QAPP. Applying a VAF of 0.1 is considered a very conservative assumption because VAFs can range from 0.1 to 0.0001 (or more) depending on groundwater-specific/soil-specific/building-specific characteristics (USEPA, 2008a). The use of a 0.1 VAF will likely overestimate the actual risk associated with VI, especially for samples that were collected near slab versus sub-slab. However, because groundwater-specific/soil-specific/building-specific characteristics are not available in Naples, for this screening assessment it is not appropriate to develop site-specific VAFs that might be less conservative.

1.5.3 Ambient Air

1.5.3.1 Representativeness of Ambient Air Data with Regard to Impact on Soil Gas Concentrations

There are uncertainties associated with the representativeness of the ambient air data with regard to their impact on soil gas concentrations. With the exception of the co-located, co-collected data, the ambient air data represent a broad area (i.e., nine study areas). Concentrations of the COPCs were considered regional because of the movement and mixing of ambient air over large areas (PIONEER, 2009). However, there is uncertainty with comparing ambient air data detected in the nine study areas to specific soil gas results (that were not collected at the same time and location) in order to determine the potential impact of ambient air on the soil gas concentrations.

Spikes in localized ambient air concentrations resulting from point and non-point combustion sources may significantly impact single soil gas samples but may not significantly impact year-long, average ambient air concentrations because of the large number of samples that were collected over the year. Consequently, analysis of the ambient air data on a micro scale is needed to correlate temporal and spatial trends in ambient air concentrations with possible anomalies in soil gas.

If concentrations of a chemical in ambient air were homogenous over space and time (and there was not a subsurface source), then the shallow soil gas concentration measured in "aerobic" soil should be equal to or less than the ambient air concentration. However, chemical concentrations in ambient air can change significantly over space and time. For example, some chemicals in ambient air have predictable cycles that are tied to automobile exhaust. Concentrations for these chemicals peak in urban areas twice-a-day during the morning and evening commutes. In order to reduce the impact of the potential heterogeneity in ambient air concentrations many VI investigators recommend collecting co-located and co-collected sample soil gas and ambient air samples. However, this does not completely eliminate all confounding factors. For example, since concentrations in ambient air and soil gas are not in equilibrium, it is expected that there will be "latency" in the movement of chemicals from one location to another. This "latency" is impacted by a number of processes (e.g., diffusion rate, barometric pumping, advection, soil moisture content, etc). Therefore, even though concentrations were measured at the same place and same time for soil gas and ambient air, the concentrations may be different because the system is not in equilibrium and also because it is feasible that the localized ambient air concentration has recently been impacted by a release from point or non-point sources (a spike in automobile exhaust during rush hour, sporadic agricultural burning, sporadic trash burning, et cetera).

Because of the limitations of the data, decision criteria for the primary lines of evidence were established to maximize protectiveness and err toward presuming a COPC was associated with a subsurface VI source rather than not. This conservative default position was retained by requiring an average soil gas to ambient air ratio of one or less to indicate a Non-VI (i.e., ambient and/or indoor air) source. The same, stringent criterion was used for site-specific (co-collected and co-located) data. Within the co-located data, mean and median soil gas to ambient air ratios of one or less were used as evidence of a Non-VI source. In reality, based on the inherent variability of the data discussed above, a soil gas to ambient air ratio of one or less may over-predict an association with a subsurface VI source. In other words, a chemical with a soil gas to ambient air ratio of 50 is much more likely associated with a subsurface soil gas VI source than a chemical with a soil gas to ambient air ratio of one.

1.5.4 Volcanic Activity

The potential contribution of volcanic activity to soil gas concentration was evaluated and it was determined that the potential contribution could not be quantified (see Appendix E for a detailed discussion of the potential contribution of volcanic activity to soil gas concentrations in Naples, Italy).

1.6 CONCLUSIONS AND RECOMMENDATIONS

1.6.1 Conclusions

The purpose of this Memo was to evaluate multimedia environmental data collected as part of the NPHE to identify inhalation COPCs that may be associated with a subsurface VI source versus other Non-VI sources (i.e., above-ground sources in ambient air and/or indoor air). It was not possible to differentiate between chemicals potentially resulting from poor waste disposal practices (dumping/burning of trash and hazardous waste) and other sources in this evaluation. Hence the focus of this Memo is to determine whether or not chemical concentrations found in soil gas are associated with subsurface VI sources that could contribute to VI in overlying buildings. This distinction is important so that the risks can be calculated appropriately and risk-management decisions can be made.

Twenty-two COPCs were evaluated in this Memo and it is important to note that none of these were eliminated from the risk assessment. The results of this evaluation will be used to classify COPCs detected in soil gas so that the human health risks can be calculated correctly.

The list of COPCs was developed by identifying all chemicals that exceeded their cancer RSL and/or noncancer RSL for soil gas (with the exception of naphthalene and acetaldehyde [see Section 1.2.3]). These COPCs were evaluated using multiple lines of evidence and were ultimately grouped into the following categories:

Non-VI COPCs	Localized VI COPCs	Global VI COPCs
1,2-Dibromo-3-chloropropane 1,2-Dibromomethane 1,2-Dichloroethane Acrolein Chloromethane	1,1,1,2-Tetrachloroethane 1,1,2,2-Tetrachloroethane 1,2-Dichloropropane 1,3-Butadiene 1,4-Dichlorobenzene Acrylonitrile Bromoform Benzene Carbon tetrachloride Chloroform Ethylbenzene Hexane Hexachlorobutadiene Methyl-tert-butyl ether	Tetrachloroethene Trichloroethene Vinyl chloride
Notes: 1. Non-VI COPCs – COPC(s) associated with ambient air and/or indoor air sources and not with a subsurface VI source. For these COPCs, human health risks for the inhalation pathway will be calculated based on ambient air concentrations. 2. Localized VI COPCs – COPC(s) potentially associated with a subsurface VI source within a specific geographical area. Most COPCs fall into this category because subsurface VI is commonly associated with a localized release. This group also includes COPC(s) for which the determination was inconclusive. Risks for these COPCs will be calculated based on soil gas concentrations at the specific locations where soil gas concentrations exceed the site-wide 95th percentile ambient air concentration. At all other locations, the inhalation human health risks for these COPCs will be calculated based on ambient air concentrations. 3. Global VI COPCs – COPC(s) associated with a subsurface VI source at all locations. For these COPCs, there must be compelling evidence to indicate that subsurface VI is a site-wide issue. For these COPCs, human health risks for the inhalation pathway will be calculated based on soil gas concentrations.		

The results of this classification will be applied to the NPHE risk management process as follows:

- At each location, all COPCs detected in soil gas will be included in the Total Risk calculations for soil gas (i.e., Non-VI COPCs + Global VI COPCs + Localized VI COPCs) at that location.
- At each soil gas sampling location, incremental risks will be calculated to support risk management decisions as follows:
 - For Non-VI COPCs, the human health risks for the inhalation pathway will be calculated based on ambient air concentrations¹³.
 - Incremental risks for ambient air will be calculated only for chemicals with a 95% UCL on the mean that is greater than background (i.e., the 95%UCL on the mean for the 2007 U.S. Air Toxics data¹⁴).
 - For Global VI COPCs, the human health risks for the inhalation pathway will be calculated based on the soil gas concentration (presumed to be VI) at that location.
 - For Localized VI COPCs, the human health risks for the inhalation pathway will be calculated as follows:
 - If the soil gas concentration at a location is greater than the 95th percentile ambient air concentration¹⁵, the human health risks for the inhalation pathway at that location will be calculated based on the soil gas concentration (presumed to be VI) at that location.
 - If the soil gas concentration at a location is less than the 95th percentile ambient air concentration, the human health risks for the inhalation pathway at that location will be calculated based on the ambient air concentration.

Table 7 summarizes the information for each COPC and presents the number of locations where the COPC is included in the soil gas (VI) risk calculations. For Global VI COPCs, all detected soil gas concentrations at all locations will be included in the cumulative VI risk calculations for the inhalation pathway. For Localized VI COPCs only those locations with detected soil gas concentrations greater than the 95th percentile ambient air concentration will be included in the cumulative VI risk calculations for the inhalation pathway.

Table 8 presents CEFs/NCEFs, by location, for each Localized and Global VI COPC. A complete list of CEFs/NCEFs by location for all 22 COPCs is presented in Appendix D. The soil gas risk-based screening values (Soil Gas RSLs) used to calculate the CEFs and NCEFs are based on the Residential Ambient Air RSLs, which are corrected by a factor of 0.1 to account for attenuation that occurs as soil gas vapors migrate into indoor air. The cumulative CEF (and NCEF for hexane) for the VI inhalation pathway are presented for each location. Those locations determined to be unacceptable based on the risk management criteria for the NPHE (i.e., cumulative CEF greater than 10 and/or cumulative NCEF greater than one) are recommended for Risk Management Action(s) at that location. These locations are presented on Figure 6.

¹³ Ambient air risks will be determined by calculating the 95% UCL on the mean per Study Area. The Log 95% UCL on the mean will be used if the data are lognormally distributed, and the 95% UCL on the mean will be used if the data are normally distributed. The maximum detected concentration will be used if the Log 95% UCL or 95% UCL on the mean exceed the maximum detected concentration.

¹⁴ In lieu of Naples-specific background ambient air data, chemical data from ambient air samples collected from six urban cities in the U.S. (San Diego, California, Los Angeles, California, Seattle, Washington, Houston, Texas, Midlothian, Texas, and Washington DC) from the 2007 USEPA Air Toxics Database (USEPA, 2007) will be used to represent background concentrations from typical urban air.

¹⁵ The 95th percentile concentrations for ambient air are based on the entire (12 month) ambient air data set and include non-detected values.

1.6.2 Recommendations

The following recommendations are based on the information presented in this Memo:

1. For future soil gas sampling events, collect contemporaneous, co-located ambient air samples in order to facilitate evaluation of the potential contribution of chemicals in ambient air to the soil gas samples. Also, if there is a well on the property, collect a water sample from the well as it may be indicative of the chemicals present in groundwater that may contribute to VI at this location.
2. Where available, future soil gas sampling events should include:
 - a. Additional data about building characteristics (e.g., square footage, condition of concrete slab, preferential pathways),
 - b. Whether the sample is sub-slab or near slab,
 - c. Sample depth and lithology, and
 - d. Other site-specific information that might allow the VAF to be refined based on a representative subset of residences in Naples.
3. As presented in Table 8, there are a number of locations with unacceptable concentrations of chloroform in soil gas. Many of these locations are not co-located with detections of chloroform in groundwater. The laboratory and analytical data validator should perform another review of the soil gas and ambient air results for chloroform to ensure that cross-contamination has not occurred. No information is currently available that indicates that cross-contamination has occurred on these soil gas samples. However, cross-contamination for chloroform was identified in some ambient air samples on this project.
4. In future reports, all soil gas sample results should be presented with their corresponding helium leak-test results in order to provide an indication of the potential for chemicals in ambient air (for near-slab soil gas samples) or indoor air/ambient air (for sub-slab soil gas samples) to "leak" into the sample train and impact the results.
5. The TO-15 results for naphthalene and acetaldehyde were rejected and, therefore, were not included in this Memo. However, some of the "rejected" results for naphthalene and acetaldehyde were unacceptable based on the risk management criteria used in the NPHE (see Appendix F for a detailed discussion of the naphthalene and acetaldehyde data). Although these results were rejected, a work plan should be developed to collect and analyze soil gas and ambient air samples via another analytical method approved by the NPHE Team, from a statistically-significant number of locations that had "rejected" unacceptable results, to determine whether or not naphthalene and/or acetaldehyde are potentially a concern to human health.

Notes

-- No value

COPC - Chemical of potential concern.

Maximum CEF = Maximum cancer exceedance factor (Maximum detected value/Cancer RSL)

Maximum NCEF = Maximum noncancer exceedance factor (Maximum detected value/Noncancer RSL)

RSL = United States Environmental Protection Agency (USEPA) Regional Screening Level

¹Chemicals with concentrations that exceed USEPA RSL in at least one soil gas sample.

²Includes all active soil gas data, excluding data collected at United States Government-related facilities, collected between November 2008 and July 2009.

³Mean and standard deviation were calculated for detected results only.

⁴The RSL for soil gas was 10 times the RSL for ambient air to account for the attenuation that occurs as soil gas migrates into indoor air.

Table 2 - Statistical Summary of COPCs Detected in Ambient Air (ug/m³)

COPC - Chemical of potential concern

Maximum CEF = Maximum cancer exceedance factor (Maximum detected value/Cancer RSL)

Maximum NCEF = Maximum noncancer exceedance factor (Maximum detected value/Noncancer RSL)

RSL = United States Environmental Protection Agency (USEPA) Regional Screening Level

¹Chemicals with concentrations that exceed USEPA RSL in at least one soil gas sample.

²Includes all samples from United States Government-related facilities.

³Mean and standard deviation were calculated for detected results only.

⁴The data summary presented in this table for hexachlorobutadiene is based on results from both co-located and air monitoring station ambient air samples that were collected and analyzed using different methodologies.

Notes

-- = No value

AA = Ambient air

CEF = Cancer exceedance factor. NCEF = Noncancer exceedance factor

GW = Groundwater

n/a = Not analyzed

ND = Not detected

N Samples = Number of samples

RSL = Regional screening level

SG = Soil gas

ug/m³ = Microgram per cubic meter

USEPA = United States Environmental Protection Agency

¹Chemicals with concentrations that exceed United States Environmental Protection Agency (USEPA) RSL in at least one soil gas sample.

² Average ambient air and soil gas concentrations were calculated using detected data only. Average SG to Average AA Ratio is the site-wide average detected soil gas concentration over the site-wide average detected ambient air concentration

³ Soil gas to ambient air concentration ratios for co-located, co-collected data and co-located groundwater data are presented in Table C-1.

⁴ Number of exceedances is per location. In some locations more than one soil gas sample was collected at a location.

⁵ Frequency of Exceedance is the number of locations with concentrations that exceed the RSL/Total number of locations.

⁶ Typical VI COPCs are:

(1) tracked on USEPA's VI Database (USEPA, 2008).

(2) Target chemicals short-listed in New Jersey Department of Environmental Protection's regulatory VI Guidance (NJDEP, 2007).

(3) Petroleum-related chemicals commonly associated with petroleum-release sites (API, 2005).

(4) Other chemicals included in USEPA's VI Guidance but not a common VI COPC.

⁷ Background outdoor air values obtained from several sources:

(1) Table C1: New York State Department of Health (NYSDOH) 2003: Study of volatile organic chemicals in outdoor air of fuel oil heated homes (NYSDOH, 2006)

(2) Table C2: EPA 2001: building assessment and survey evaluation (BASE) database (Outdoor Air), SUMMA canister method (NYSDOH, 2006);

(3) U.S. EPA Air Toxics Database: San Diego County, California (211 Records) 2. Los Angeles County, California (458 Records) 3. King County (Seattle), Washington (137 Records) 4. Harris County (Houston), Texas (1129 Records) 5. Ellis County (Midlothian), Texas (234 Records) 7. Washington DC (150 Records). http://www.epa.gov/aqspub1/annual_summary.html (USEPA, 2007).

⁸ COPC was detected in only one sample. No average calculated.

⁹ Trichloroethene and vinyl chloride did not meet the criteria for Global VI COPC but are classified thus because they are by-products of tetrachloroethene which is a Global VI COPC

Table 5 – Classification Decision Criteria

Chemical Name		
Chemical Information:		
PRIMARY LINES OF EVIDENCE	DATA INDICATE A SUBSURFACE VI SOURCE (YES)	DATA INDICATE A NON-VI SOURCE (YES)
1. COPC Detected in Groundwater/Spatial Distribution of Groundwater is Consistent with Soil Gas?	groundwater = detected and groundwater/soil gas = spatially associated	groundwater = not detected or groundwater/soil gas ≠ spatially associated
2. Soil Gas & Ambient Air Concentration Frequency Distribution Patterns.	soil gas/ambient air distributions ≠ similar and/or soil gas frequency > ambient air frequency (in upper tail of the distribution)	soil gas/ambient air distributions = similar and/or ambient air frequency > soil gas frequency (in upper tail of the distribution)
3. Site-Wide Average Soil Gas to Average Ambient Air Ratio Greater than 1?	average soil gas to ambient air ratio > 1	average soil gas to ambient air ratio ≤ 1
4. Mean or Median Soil Gas to Ambient Air Ratio for Locations with Co-located, Co-collected Soil Gas and Ambient Air Data Greater than 1?	mean ratio or median ratio > 1	mean ratio and median ratio ≤ 1
Scoring:	Score is the total number of “yes” from each of the Primary Lines of Evidence listed above.	Score is the total number of “yes” from each of the Primary Lines of Evidence listed above.
Moving On:	If the score for the “Data Indicate a Subsurface VI Source” column is ≥ the score for the “Data Indicate a Non-VI Source” column, then the chemical is determined to be a VI COPC.	
SECONDARY LINES OF EVIDENCE (FOR COPCS ASSOCIATED WITH A VI SOURCE)	DATA INDICATE A GLOBAL VI COPC	DATA INDICATE A LOCALIZED VI COPC
1. Geographical Distribution	exceedances = widely distributed clusters	exceedances = localized clusters or anomalies
2. Frequency that Soil Gas Concentrations Exceeded the RSL	Frequency > 25%	Frequency ≤ 25%
Comments/Discussion:	Additional information described here	
Classification	Global VI COPC, Localized VI COPC, or Non-VI COPC

Notes

-- No value

n/a = Not analyzed for in groundwater

COPC - Chemical of potential concern

RSL = United States Environmental Protection Agency (USEPA) Regional Screening Level. The value presented is the minimum of the cancer and noncancer RSLs.

Bolded values identify groundwater reporting limits that are not protective of the Vapor Intrusion (VI) pathway based on the migration of COPCs in groundwater to soil gas to indoor air, assuming Henry's law and an attenuation factor of 0.01.

¹ Chemicals with concentrations that exceed USEPA RSL in at least one soil gas sample.

² The RSL for soil gas was 10 times the RSL for ambient air to account for the attenuation that occurs as soil gas migrates into indoor air.

³ Calculated using the Minimum USEPA RSL for soil gas and Dimensionless Henry's Law Constant. An attenuation factor of 0.01 was used to account for the attenuation that occurs as soil gas migrates from the water table interface to sub-slab soil gas. This attenuation factor is consistent with the empirical attenuation factor for tetrachloroethene (PCE) at Location 0488 where PCE was detected in groundwater at 0.533 ug/L and in soil gas at 3.93 ug/m³. Using 0.533 ug/L * Dimensionless H-Law (0.753) * 1,000 (L/m³) = 401 ug/m³. The attenuation factor for PCE in shallow soil gas and PCE in soil gas at the water table interface = 3.93 ug/m³ / 401 ug/m³ = 0.01.

**Table 7 - Summary of COPC Classification and
Number of Locations Included in VI Risk Calculations**

Notes

-- COPCs classified as Non-VI COPCs are not included in VI risk calculations but are included in ambient air risk calculations.

COPC - Chemical of potential concern

CEF = cancer exceedance factor (Detected value/Cancer Soil Gas RSL)

NCEF = Noncancer exceedance factor (Detected value/Noncancer Soil Gas RSL)

VI = Vapor Intrusion

Minimum Soil Gas RSL= United States Environmental Protection Agency (USEPA) Regional Screening Level. The RSL for soil gas was 10 times the RSL for ambient air to account for the attenuation that occurs as soil gas migrates into indoor air. The minimum of the cancer or noncancer RSL is provided.

¹ 95th Percentile Ambient Air Screening Value - This is the 95th percentile of the site-wide ambient air concentrations (detected and non-detected data) collected over a period of 12+ months. Only soil gas concentrations for localized VI COPCs exceeding this threshold are included in the CEF/NCEF calculations for VI.

**Table 8 – CEFs and NCEFs Calculated from
Soil Gas Concentrations for Global and Localized VI COPCs**

# of Locations COPC is Included in VI Risk Calculations		5	5	8	9	11	11	35	3	4	95	82	11	6	177	43	1	6		2	
# of Locations with CEF > 10 and/or NCEF > 1		0	0	1	0	1	0	5	0	1	18	2	0	0	37	1	0	2	73	2	73

Notes:

CEF = Cancer exceedance factor (Detected Soil Gas Concentration/Cancer RSL)

COPC = Chemical of potential concern

NCEF = Noncancer exceedance factor (Detected Soil Gas Concentration/Noncancer RSL).

RSL = United States Environmental Protection Agency (USEPA) Regional Screening Level

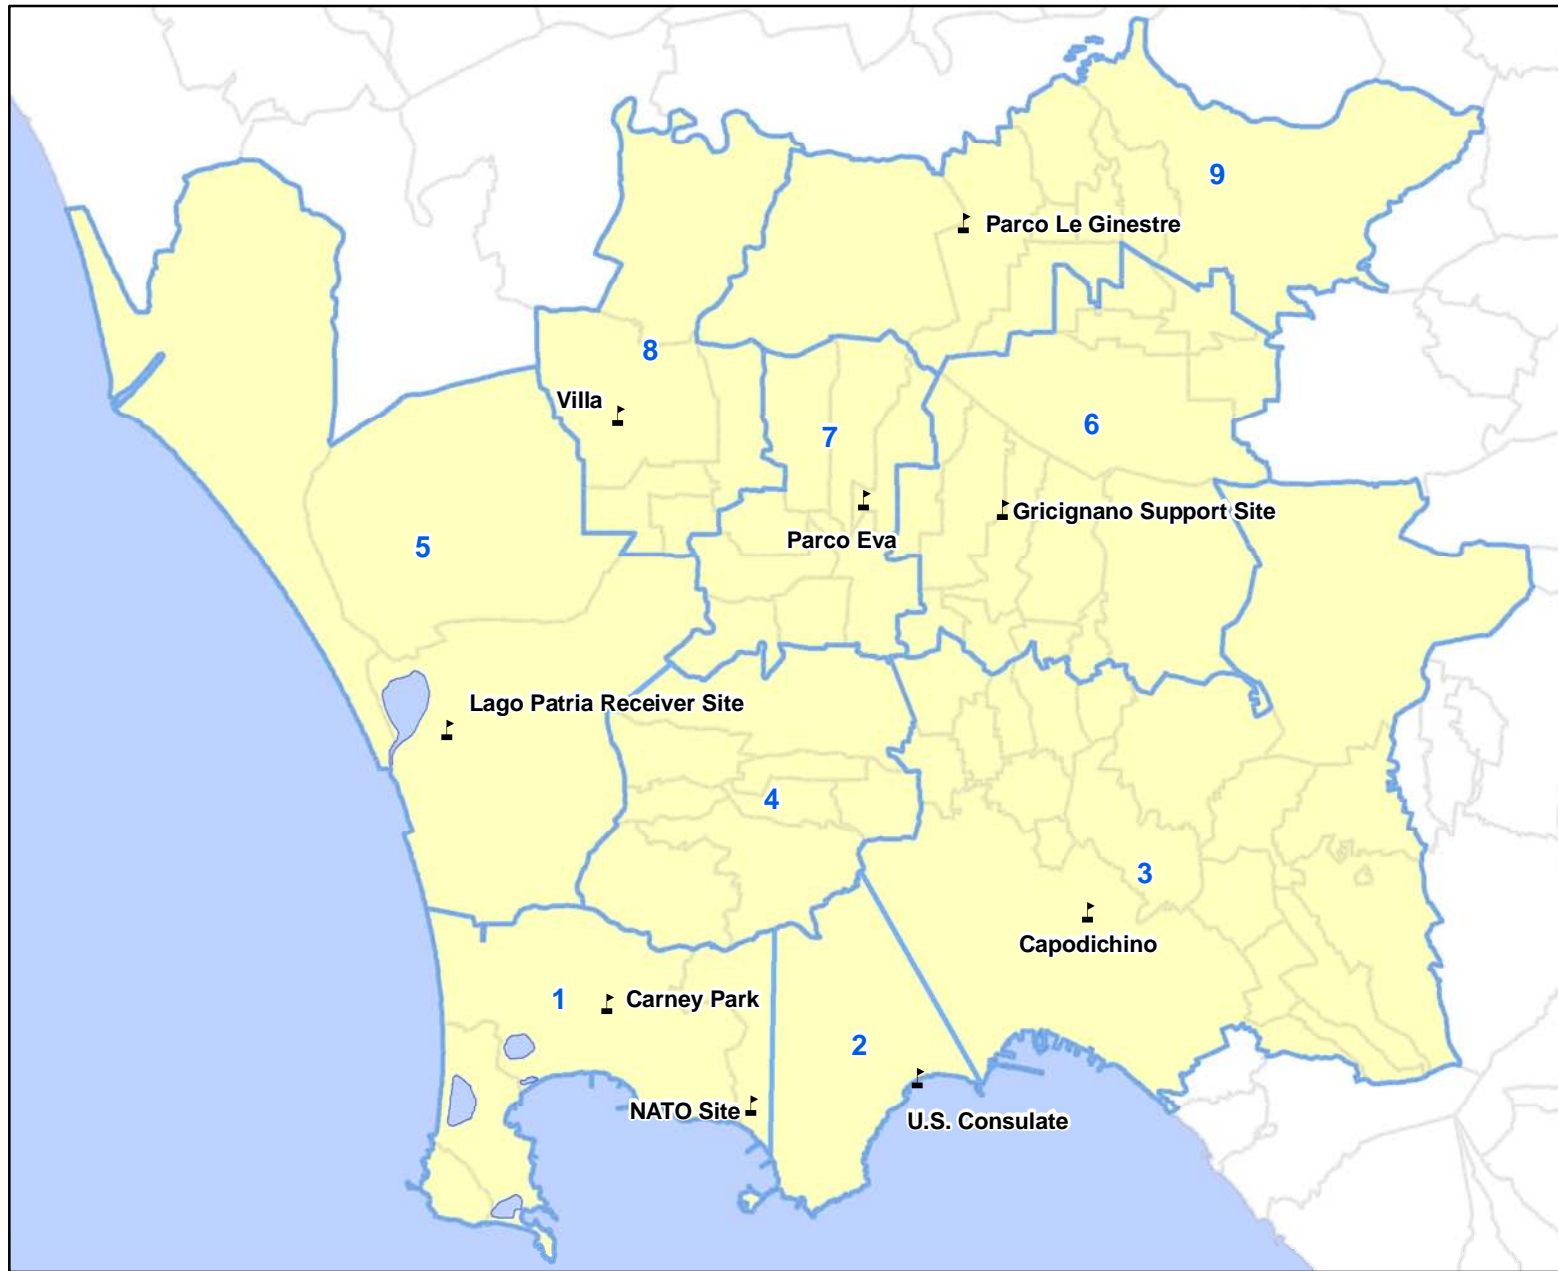

VI = Vapor Intrusion

The RSL for soil gas was 10 times the RSL for ambient air to account for the attenuation that occurs as soil gas migrates into indoor air.

¹ Only soil gas concentrations for Localized VI COPCs exceeding this threshold are included in the CEF/NCEF Calculations for Vapor Intrusion. Global VI COPCs are included in all VI Calculations regardless of soil gas concentration.

22.88 Bolded cells represent locations where the CEF was greater than 10 or NCEF for Hexane was greater than 1.

Notes:

Groundwater samples were collected from either tap water (not public water supply), private wells, or irrigation wells. See Section 1.1 for description of data types.

Qualifiers:

J = Estimated

U = Not detected

UU = Not detected, estimated

Ratio is the co-located, co-collected soil gas concentration over the ambient air concentration.

1,3-butadiene, acrylonitrile, and hexane were not analyzed in groundwater samples.

-- = Not analyzed

ND = Not detected, ratio not calculated

Technical Memo – Summary of Soil Gas Issues Related to Areas of Volcanic Activity

TECHNICAL MEMORANDUM

SUMMARY OF SOIL GAS ISSUES RELATED TO AREAS OF VOLCANIC ACTIVITY

Tetra Tech NUS, Inc. (Tetra Tech) is the Prime Contractor to the United States Navy participating in an Environmental Testing Support Assessment (ETSA) in the Campania region of Naples, Italy. The overall objective for the ETSA is to assess the potential health risks from past and ongoing illegal and illicit waste disposal practices to United States military and civilian personnel who work and reside in this region. For the purposes of the ETSA, the investigation area includes nine Study Areas, as depicted on Figure 1.

As part of the ETSA, Tetra Tech is sampling various media including soil gas, ambient air, and tap water (with sources including groundwater, municipal water systems, and taps drawing blended water from both groundwater and municipal sources). Air sampling activities included collecting ambient air samples for volatile organic compound (VOC) analysis over the course of 1 year, comprising sampling multiple times per month at each of nine air-monitoring stations. Tetra Tech collected soil gas samples at various properties throughout the nine study areas determined by VOC concentrations, typically one sample per property. The locations of sampling of soil gas and ambient air did not always coincide.

Elevated concentrations, greater than United States Environmental Protection Agency (USEPA) air quality criteria, of VOCs were present in soil gas and ambient air during this ETSA. The objective of this Technical Memorandum is to present information on a potential volcanic source of VOCs detected in ambient air and soil gas. These compounds contribute to human health risk to United States personnel who work and reside in the Naples region.

The mean soil gas concentrations of environmentally significant VOCs consistently exceed the mean concentrations of the same VOCs in ambient (above-ground) air. Soil gas is the vapor found within the spaces between soil particles in the unsaturated zone of overburden soil, where the constituents are in dynamic exchange with adsorbed compounds on soil particles and dissolved in soil water content. These compounds might undergo consumption, creation, and modification by processes acting within the soil like microbial activity, plant respiration, and inorganic chemical processes.

Barometric pumping, which is the repeated movement of ambient air into and out of soil vapor as a result of changing barometric pressure, was considered as an explanation for the observed concentration differences between soil gas and ambient air. Barometric pumping, however, does not explain how soil gas concentrations could be greater than ambient air concentrations by a factor of two or more; therefore, Tetra Tech began an evaluation of other potential contributing factors and explanations for air and tap water VOC results. Additionally, it is also unlikely that soil gas concentrations would be measurable in ambient air because of dilution. This evaluation suggests that the volcanic activity of the Naples region may be one of the possible sources that could be contributing to the detection of VOCs in soil gas. Other possible sources include shallow microbial activity and anthropogenic contamination sources. Microbial activity and plant respiration are a less likely contributing factor because most samples came from covered soil, and anthropogenic contamination would create varying chemical profiles at different sampling sites.

Several scientific literature references document the presence of multiple VOCs in emissions associated with active volcanoes, implying that the observed soil gas VOC concentrations may be due, at least partially, to volcanic activity. Although it is likely that other sources of contamination are also potentially responsible for detections of VOCs in both ambient air and soil gas, the types of VOCs detected during this investigation are similar to VOCs detected in geothermal/hydrothermal emissions referenced in literature.

Mount Vesuvius, a quiescent but active volcano, is located approximately 9 kilometers east of Naples. Ongoing active monitoring of volcanic activity indicators on Vesuvius and the entire region by the Italian

**TECHNICAL MEMORANDUM
SUMMARY OF SOIL GAS ISSUES RELATED TO
AREAS OF VOLCANIC ACTIVITY**

Osservatorio Vesuviano, the oldest volcano observatory in the world, documents the activity shown by seismic tremors, significant ground deformation, and the strong presence of magmatic gases. The strong volcanic influence in the region is prevalent by the presence of numerous hydrothermal sites and hot springs. Volcanic influence affects most of the Campania region, based on the presence of hydrothermal activity such as hot springs, a subset of which are shown in Figure 1. Furthermore, the entire region has high ground heat flow and emissions of magmatic carbon dioxide, and seismic studies indicate the presence of magma pockets under most of the region (Gasparini, 2001). The region near the Gulf of Naples, known as the Phlegraean Fields or Campi Flegrei, is an area of intense hydrothermal activity. Other locations east and northeast of Naples such as Villamaina and Telese contain thermal spas or hot springs that provide evidence of regional volcanic influence. Additionally, hydrothermal activity is present in the Tuscany region located in northern Italy. As shown on Figure 1, the nine ETSA study areas are located west and northwest of Mount Vesuvius.

This Technical Memorandum briefly discusses the categories of VOCs, as trace organic components of volcanic emissions, documented to be associated with volcanic activity and presents lines of evidence that show that volcanic activity may be a contributor to soil gas and ambient air VOC concentrations detected during ETSA sampling. Volcanic activity involves magma in the subsurface, and this hot magma creates a temperature gradient of more than 600°C at the magma surface that decreases to ambient temperatures at the ground surface. At one or more points along this vertical temperature gradient, naturally occurring organic material such as petroleum and organic acids in bedrock, carbon from carbon dioxide, and simple hydrocarbons contained naturally in magma, combine to form naturally occurring halogenated compounds such as sodium chloride or calcium fluoride, and other materials may react chemically to form halogenated and non-halogenated VOCs (Schwandner et al., 2004). VOCs thus formed would migrate upward under thermal gradients and diffusion mechanisms. Mean VOC concentrations in ambient air would necessarily be equal to or less than associated mean soil gas concentrations because ambient air would dilute VOCs emanating from soil gas in the ground.

ETSA DATA PRESENTATION

ETSA soil gas and ambient air sample results indicate that many VOCs had not been detected or were rarely detected. Table 1 lists the mean concentrations of a group of representative VOCs detected during ETSA sampling activities in both ambient air and soil gas across all nine study areas. Of the compounds in Table 1, acrolein and 1,2-dichloropropane have mean ambient air concentrations greater than mean soil gas concentrations, but the differences are slight. The tetrachloroethene concentration in soil gas is 30 times the ambient air mean concentration, but this compound likely originates from non-volcanic contaminant sources. Mean concentrations of the seven other VOCs are also markedly greater in soil gas than in ambient air, and these compounds are often associated with volcanic emissions from soil gas and low- temperature fluids as noted in literature references. These VOCs are often associated with other sources of contamination such as fuel leaks/spills and chlorinated solvents.

AREAS OF VOLCANIC ACTIVITY**

**Table 1
Summary of Naples VOC Concentrations**

VOC	Mean Ambient Air Concentration⁽¹⁾ (µg/m³)	Mean Soil Gas Concentration (µg/m³)
Toluene	8.82	29.9
Acetaldehyde	-- ⁽²⁾	45.1
Chloroform	0.22	9.4
Benzene	4.15	17.2
Acrolein	2.94	1.80
Trichlorofluoromethane	1.68	50.1
1,2-Dichloropropane	4.7	3.2
Tetrachloroethene	4.1	122
Styrene	0.78	58.6
Naphthalene	4.9 ⁽³⁾	11.7

Concentrations from USEPA Method TO-15, except as noted in footnotes below.

- 1 Mean ambient air concentrations determined from sampling months 1 through 6.
- 2 Acetaldehyde ambient air concentrations were determined using USEPA Method TO-11. Soil gas results reported using USEPA method TO-15.
- 3 Naphthalene ambient air values shown were analyzed using USEPA method TO-15, but do not cover the entire 6- month air sampling period.

**TECHNICAL MEMORANDUM
SUMMARY OF SOIL GAS ISSUES RELATED TO
AREAS OF VOLCANIC ACTIVITY**

Table 2 lists the mean concentrations of a group of representative VOCs detected in ambient air and soil gas across all nine study areas. Mean soil gas concentrations for chloroform, styrene, trichlorofluoromethane, and tetrachloroethene were greater than ambient air concentrations in samples from all nine study areas. Using mean concentration data, Tetra Tech calculated ratios of soil gas to ambient air concentrations and used these values to graphically compare the data sets.

Figures 2 through 9 present mean VOC concentration ratios (soil gas/ambient air) for each study area. Ratios greater than unity indicate higher concentrations in soil gas, a characteristic consistent with underground sources such as fuel leaks/spills, groundwater contamination, and volcanic emission origins. The ratios for chloroform, styrene, trichlorofluoromethane, and tetrachloroethene are greater than unity in all nine study areas. Chloroform, styrene, trichlorofluoromethane, and tetrachloroethene were present in more than half of the ambient air samples in the first six months. Benzene and toluene ratios are greater than unity in five and six study areas, respectively, and both of these compounds were present in all of the ambient air samples in the first six months.

**TECHNICAL MEMORANDUM
SUMMARY OF SOIL GAS ISSUES RELATED TO
AREAS OF VOLCANIC ACTIVITY**

**TECHNICAL MEMORANDUM
SUMMARY OF SOIL GAS ISSUES RELATED TO
AREAS OF VOLCANIC ACTIVITY**

The main groups of VOC volcanic gaseous emissions relevant to the current Naples ETSA investigation include aromatic hydrocarbons, chlorinated or halogenated hydrocarbons, oxygenated organic compounds, and alkanes. The following presents a subset of literature summaries evaluated for this Technical Memorandum:

- Two literature references identify aromatic hydrocarbons as being present in volcanic emissions at varying concentrations (Schwandner et al., 2004 and Tassi et al., 2008). Schwandner et al. identified styrene and naphthalene at fumaroles and near upper and lower crater flanks. The distances cited in the Schwandner report from the volcanic crater were up to 1,000 meters. Mean concentrations reported by Schwandner et al. for styrene and C2- substituted benzenes were 359 parts per billion by volume (ppbv) and 182 ppbv, respectively. These concentrations are equivalent to approximately 1,530 $\mu\text{g}/\text{m}^3$ and 790 $\mu\text{g}/\text{m}^3$ for the respective compounds.

In the study by Tassi et al., aromatic hydrocarbon concentrations in soil gas were approximately 3.9 percent of the volatile organic components detected in gaseous emissions. In Tassi et al., aromatic compounds made up 49.5 percent of the total VOCs associated with hydrothermal fluids and 8 percent in low-temperature fluids of gas emissions at a volcano in Tuscany, Italy. Tassi et al. did not present percent relative abundance data for VOCs in volcanic emissions; however, concentrations are sufficiently high to detect using routine analytical techniques.

Table 3 summarizes several aromatic compounds as reported by Tassi et al. (2008) and compares the concentrations to the means detected in Naples soil gas samples.

Tassi et al. also references a very high concentration of benzene in the dry-gas phase of hydrothermal fluid discharges (93,800 ppbv). Benzene was also present in low-temperature fluids in the Tuscany region at 16 ppbv. These data suggest the possibility that volcanic activity is a contributing source of aromatic VOCs in soil gas and ambient air. Table 3 details that the mean concentrations reported in Naples soil gas samples were mostly greater than those reported by Tassi, although Tassi et al. includes data from only one soil gas sample.

As noted by Tassi et al., hydrothermal fluids from three distinct systems (Yellowstone, USA; Tendaho, Ethiopia; Tatun, Taiwan) and low-temperature fluids in Tuscany, Italy, contained every compound in Table 3 except for styrene (as mean concentrations). As reported in Schwandner et al., 9 of 14 samples of soil gas emissions from Vulcano, Aeolian Islands, Italy, had detectable concentrations of styrene. These data suggest that, despite geographical location differences, common processes such as below ground combustion sources and carbon dioxide flux associated with volcanic systems are responsible for the formation of VOCs from different subduction zone volcanoes.

**Table 3
Soil Gas VOC Concentrations**

Aromatic VOC	Tassi Report		Naples Soil Gas Mean ($\mu\text{g}/\text{m}^3$)
	Soil Gas (ppb by vol)	Soil Gas ($\mu\text{g}/\text{m}^3$)	
Naphthalene	0.2	1.0	11.7
Benzene	13	41.5	17.2
Toluene	3	11.3	29.9
m-p-xylenes	2	26.1	43.0
o-xylene	0.3	3.9	16.5
Styrene	0.1	0.32	58.6
Ethylbenzene	0.1	0.43	21.0

- Halogenated or chlorinated hydrocarbons include compounds containing fluorine, chlorine, bromine, and iodine. Schwandner et al. documents the presence of the following compounds in fumarole

**TECHNICAL MEMORANDUM
SUMMARY OF SOIL GAS ISSUES RELATED TO
AREAS OF VOLCANIC ACTIVITY**

emissions: methyl iodide, methyl bromide, methyl chloride, chloroform, trichlorofluoromethane, bromoethane, chlorobenzene, and dichlorobenzene. The mean concentrations reported for chloroform and trichlorofluoromethane were 27.5 ppbv and 0.6 ppbv, respectively. These concentrations are equivalent to approximately $130 \mu\text{g}/\text{m}^3$ and $3 \mu\text{g}/\text{m}^3$ for the respective compounds.

Tassi et al. reported the presence of halogenated VOCs such as trichloroethene, 1,2-dichloropropane, chlorohexane, and dichlorobenzenes in soil gas and hydrothermal fluid emissions. In Tassi et al., halogenated compounds made up 5.8 percent of the total VOCs associated with soil gas and 4.5 percent in low-temperature fluids of gas emissions at a volcano in Tuscany, Italy. Tassi et al. also reported 1,2-dichloropropane in hydrothermal fluids at a concentration of 906 ppbv. This compound was present across all nine study areas in ambient air during the Naples air investigation.

Matthias et al. (2006) investigated halocarbon origins from fumarole locations around the Momotombo volcano in Nicaragua and detected a variety of halogenated organic compounds at concentrations greater than in ambient air.

- Oxygenated organic compounds such as ketones and aldehydes, organic acids, alcohols, and esters were present at relatively high concentrations in soil gas samples and in fluids from low-temperature systems in both the Tassi et al. (2008) and Schwandner et al. (2004) studies. Schwandner et al. documented the percent relative concentrations of oxygenated compounds such as acetone and acetaldehyde in soil gas samples as a function of distance from the crater and fumaroles. Acetone concentrations correlate reasonably well with the measured carbon dioxide flux, indicating a volcanic origin. There is a strong positive correlation of compound concentration with CO_2 flux.

Schwandner et al. detected acetaldehyde and acrolein in volcanic gaseous emissions, although the report did not document specific concentrations. The Report on Carcinogens, Eleventh Edition, identified acetaldehyde as a product of combustion, and this VOC occurs naturally in animal wastes and volcanic emissions. The Report on Carcinogens also described acetaldehyde detections in emissions from power plants that burn fossil fuels and from photo-oxidation of hydrocarbons in the atmosphere.

The area west of Mount Vesuvius is a high carbon dioxide release and enhanced rock leaching region. CO_2 and resistivity profiles suggest active faults and/or degassing at shallow depths. The south-southwestern sector of Vesuvius is the main degassing system of the volcano (Federico et al., 2001). Based on these observations, Tetra Tech expects acetaldehyde and acrolein generation in the ETSA study areas.

- Alkanes generally comprise the majority of VOCs in low-temperature (50 to 400°C) volcanic gases, approximately 60 percent. The presence of alkanes in ETSA samples has not been a significant human health concern, but hexane was present in soil gas samples. Hexane is a prominent hydrocarbon found in a variety of low-temperature volcanic and hydrothermal degassing sites around the world (Capaccioni et al., 1993; Kiyoshu and Asada, 1995). VOCs detected in some Naples soil gas samples include alkanes such as propane, butane, and iso-butane.

Tassi, et al (2008) reported C_2 - C_5 alkanes in soil gas samples near the El Chichon volcano in Chiapas, Mexico. Taran and Gigenbach (2003) reported that light alkanes such as CH_4 and C_2H_6 were present at shallow depths in volcanic and hydrothermal systems by thermal decomposition of organic matter. Samples from a fumarole showed an abundance of lower n-alkanes (less than C_{10}).

Because groundwater is in contact with soil gas at the interface, VOCs detected in soil gas may originate from groundwater. Tetra Tech compared concentrations of VOCs detected in soil gas in the nine ETSA study areas to concentrations in groundwater samples. In some cases, as shown in Table 4, the groundwater sample detection limits were not low enough to enable detection of these VOCs at estimated concentrations based on detected soil gas concentrations. For example, using an acrolein mean concentration in soil gas of $1.8 \mu\text{g}/\text{m}^3$ and applying Henry's Law, the equilibrium concentration in water would be approximately $0.35 \mu\text{g}/\text{L}$, whereas the method detection limit (MDL) for acrolein in water for the

**TECHNICAL MEMORANDUM
SUMMARY OF SOIL GAS ISSUES RELATED TO
AREAS OF VOLCANIC ACTIVITY**

ETSA is 0.40 µg/L. Table 4 summarizes mean soil gas concentrations and equates the concentrations to approximate water-equivalent concentrations. This table demonstrates that the lack of VOC detections in groundwater is not evidence to eliminate groundwater as the source of VOCs in soil gas.

**Table 4
VOC Soil Gas and Water Equivalent Comparison**

Compound	Mean Soil Gas Concentration (µg/m³)	Approximate Water Equivalent Concentration ⁽¹⁾ (µg/L)	Water MDL (µg/L)
Acrolein	1.8	0.35	0.40
Benzene	17.2	0.08	0.05
Chloroform	9.4	0.065	0.09
1,2-Dichloropropane	3.2	0.03	0.15
Naphthalene	11.7	0.6	0.19
Styrene	58.6	0.52	0.08

¹ Assumes that soil gas and groundwater are in equilibrium (i.e., no attenuation factors were utilized).

Although some compounds have calculated equivalent water concentrations greater than MDLs, actual water concentrations may be much lower because groundwater and soil gas may not be in equilibrium.

SUMMARY AND CONCLUSIONS

Tetra Tech detected VOCs in soil gas samples collected from a number of locations in the nine study areas. The physical and chemical data presented from various independent researchers indicate that many of these same VOCs are in diffuse gaseous emissions from subsurface volcano-related sources. The articles reviewed identify various trace VOCs from different volcanoes including Vulcano in Italy, El Chichon in Mexico, and Momotombo in Nicaragua. The reporting in the literature of the same VOCs in gaseous emissions from different volcanoes in different parts of the world suggests the possibility that volcanic activity may be a source of the VOCs found in soil gas and ambient air samples in the study areas. However, many other sources are likely to contribute to the ubiquitous presence of these VOCs in ambient air in this region.

The VOCs detected in the soil gas samples are also commonly present near locations where leaks, spills, land-filling and illegal dumping operations occur. Considering the possible contribution of these other sources and given the limited sub-surface investigation results, it is not possible to quantify the contribution of volcanic emissions to the observed soil gas VOC concentrations. Furthermore, the sampling objectives of this study did not seek to determine the VOC contribution caused by the influence of the volcanic system in the region. In order to determine the possible contribution of volcanic emissions to the observed soil gas and ambient air VOC concentrations, Tetra Tech consulted with Dr. Florian Schwandner, an expert volcanologist. Dr. Schwandner was able to examine some of the data for the ETSA study and he found no contradiction of a volcanic signal in the data provided. However, Dr. Schwandner did indicate that Tetra Tech needs considerably more information, such as carbon dioxide flux data, heat flow, oxygenated compounds, alkane/alkene ratio data, and biomarkers to identify the presence of a volcanic source. Therefore, despite the similarities between the VOCs detected in this study and the VOCs identified in scientific research of volcanic emissions in several geographical regions, sufficient data are not available at this time to determine whether volcano-related emissions contribute to the soil-gas or ambient air VOCs. Thus, Tetra Tech cannot prove or disprove the assertion that volcanic activity, as a source of heating and combustion, may be contributing to the presence of VOCs in the subsurface environment of the ETSA study areas.

Technical Memo – Naphthalene and Acetaldehyde Method Comparison

SUMMARY

Naphthalene and acetaldehyde are among the compounds that TtNUS is monitoring as a part of the Environmental Testing Support Assessment (ETSA) for NSA Naples, Italy. For each of the compounds, the laboratory has reported results using the EPA-approved method and an alternative method. Data reviewers observed some apparent inconsistencies between the results, which raised questions about the appropriate data to use. TtNUS has performed an evaluation of the data and associated analytical methods and has concluded that use of data from the alternative methods in place of data from prescribed EPA methods is not technically supportable. TtNUS recommends the use of TO-13A naphthalene data and TO-11A acetaldehyde data for risk assessment purposes. Bullets that follow present key points from the following detailed discussions:

Naphthalene:

- TtNUS' position is that the use of TO-15 for the analysis of naphthalene in soil gas samples is inappropriate.
- To date, TtNUS cannot find an EPA method validation study for use of TO-15 for naphthalene analysis.
- TtNUS questions the usability of TO-15 naphthalene data as reported at this time for soil gas risk assessment purposes, because of a lack of quantitative data supporting its validity.
- Naphthalene's vapor pressure is below the limit for which TO-15 is applicable.
- EPA does not list naphthalene as a target compound in method TO-15, which is an indication that the method may not produce reliable naphthalene results.
- The Project QAPP prescribes method TO-13A for ambient air analyses, instead of TO-15, and so its use would violate the QAPP.
- A 60% recovery for laboratory proficiency test samples using method TO-13A supports the validity of the method's results. There are no proficiency test results for TO-15 to evaluate its validity for naphthalene analyses.
- The laboratory detailed technical objections with the use of TO-15 to analyze samples for naphthalene
- Table 1 shows TO-15 recoveries an order of magnitude lower than TO13A and there are no other quality control data to demonstrate the validity of the TO-15 performance.

Acetaldehyde:

- TtNUS' position is that the use of TO-15 for the analysis of acetaldehyde is inappropriate.
- To date, TtNUS cannot find specific EPA method validation information regarding TO-15 applicability for acetaldehyde analysis.
- To date, no method validation for use of TO-15 acetaldehyde analysis has been provided.
- PHC prescribed use of method TO-11A for aldehydes and therefore, that is the method listed in the QAPP
- Use of two separate methods for acetaldehyde was unintended, inappropriate, and without a technical basis.
- Interferences may affect acetaldehyde results by TO-15 that could lead to falsely high results.

- An 80% recovery for laboratory a proficiency test sample using method TO-11A supports the validity of the method's results. There are no proficiency test results for TO-15 to evaluate its validity for acetaldehyde analyses.
- Quality control results for acetaldehyde by TO-11A support the validity of the data.

BACKGROUND

Naphthalene and acetaldehyde are among the compounds that TtNUS is monitoring as a part of the Environmental Testing Support Assessment (ETSA) for NSA Naples, Italy. For each of the compounds, the laboratory has reported results using the EPA-approved method and an alternative method: TO-13A (EPA method) and TO-15 for the naphthalene, and TO-11A (EPA method) and TO-15 for acetaldehyde. Data reviewers observed some apparent inconsistencies between the results, which raised questions about the appropriate data to use. TtNUS has performed an evaluation of the data to determine whether it would be appropriate to use data from those alternative methods for risk assessment and decision-making purposes, rather than using data from the prescribed EPA methods.

Naphthalene

TtNUS has been performing naphthalene analyses in ambient air for the ETSA using the EPA-prescribed method TO-13A, a semi-volatile organic compound technique that uses a polyurethane foam (PUF) collection medium followed by gas chromatography/mass spectrometry (GC/MS) analysis. TtNUS selected this technique by applying a DQO process in development of the ETSA QAPP. Method design was specific for the sampling and analysis of semi-volatile compounds, such as naphthalene, in ambient air. Consequently, the method is supported by detailed validation studies that include quantification of quality parameters such as bias, precision, and accuracy.

Collection and analysis of soil gas samples used TO-15, a technique that uses a canister sample collection followed by GC/MS for the analysis of volatile organic compounds (VOCs). Project personnel identified a desire to obtain a measure of the naphthalene in soil gas samples, ultimately selecting TO-15 for this analysis. In addition to the soil gas samples, the team later concluded that it would be appropriate to collect ambient air samples located just outside the locations where the soil gas samples were collected. Note that these samples are not the same ambient air samples collected at the monitoring stations in the nine ETSA study areas and the sampling locations are not co-located with those monitoring stations. In reviewing the TO-15 results, team members identified what appeared to be inconsistencies between the TO-15 data and the TO-13A data from the monitoring stations. The TO-15 results were much higher than the TO-13A results. Because of the distances between the sampling locations, a direct correlation is not possible, but the data did raise questions about preferred method use for naphthalene sampling and analysis.

The compound list for TO-15 does not include naphthalene and the method scope indicates that it is applicable to VOCs, defined as having a vapor pressure greater than 0.1 torr at 25°C and 760 mm Hg. Naphthalene has a vapor pressure of 0.08 torr and so is not a VOC by definition in this method. Because of this, we assume there has been no EPA-approved method validation study using this method for naphthalene and so quality parameters such as bias, precision, accuracy, and interference potential are unquantified. When TtNUS requested that the laboratory analyze for

naphthalene using TO-15, laboratory objected noting the vapor pressure limitation, the fact that naphthalene is a solid at room temperature, and that it is not a method-listed compound.

TtNUS conducted a limited comparison study to aid in determining whether the TO-15 method results for naphthalene and acetaldehyde would be appropriate for risk assessment and decision-making purposes, instead of the results from the EPA-specified methods. The study employed a simple sampling approach using certified gas standards prepared by Scott's Specialty Gases at Tetra Tech's request. Scott's Specialty Gases prepared acetaldehyde and naphthalene standards at concentrations (both at 110 parts per billion by volume) comparable to ETSA study results observed to date. Varying sampling configurations using Tedlar bags, canisters, and sorbent tubes, pre-loaded with the certified acetaldehyde standard, were part of the comparison test. Additional sampling configurations using Tedlar bags, canisters, and PUF media, pre-loaded with the certified naphthalene standard were also set up for the comparison testing. A known volume of gas, added to each sampling configuration, established either the concentration or amount loaded of the standard compound. Discussion of acetaldehyde results are below. Table 1 presents the results of the naphthalene comparison. Both techniques produced low recoveries, but the TO-15 recoveries are approximately an order of magnitude lower than that of TO-13A. The low recoveries for both methods may be indicative of a problem with the design or implementation of the study. Regardless, these data do not support the use of TO-15 data.

As a part of their quality assurance process, the laboratory analyzed a naphthalene proficiency test sample provided by ERA, using method TO-13A. The recoveries for naphthalene for TO-13A were 55.5% and 64.2%, which are well within the acceptance limits for the method. This provides strong evidence of the validity of the laboratory's application of TO-13A for the naphthalene. Because the TO-15 is not an approved method for naphthalene, naphthalene was not a component of the proficiency-test sample from ERA and so there are no proficiency results available to evaluate the method.

The results of the comparability study might indicate that neither procedure is valid for naphthalene analyses nevertheless; readers must recognize that the study was very limited and the project team did not have the opportunity to repeat the study or perform additional measurements to investigate the cause of the low recoveries. However, the TO-13A proficiency test samples as well as the quality control data generated by the laboratory for method TO-13A provided a reasonable level of confidence in the data. There are no independently certified standard data supporting the validity of the TO-15 naphthalene results.

TtNUS concluded that TO-15 naphthalene results should not be used for risk assessment purposes. In the absence of compelling technical evidence that data from an alternative technique is superior, such data should not be used in place of data generated by a prescribed procedure. TO-15 has not been tested or validated for naphthalene analysis and the laboratory does not have independently certified quality control standard data supporting its validity.

Acetaldehyde

In applying the DQO process for the development of the ETSA QAPP, the project team selected the TO-11A, the EPA-prescribed method, for the analysis of acetaldehyde in ambient air. TO-11A uses sorbent-tube sample collection followed by high-performance liquid chromatography analysis. This method, developed specifically for the analysis of carbonyl compounds in ambient air, including aldehydes and ketones, is consistently used for ambient air monitoring. Consequently,

the EPA has completed detailed method validation studies directly applicable to acetaldehyde and has quantified quality parameters such as bias, precision, and accuracy, as well as for the affects of potential interferences.

Ambient air samples are also collected and analyzed to monitor the concentrations of other VOCs, using TO-15. The method's list of analytes includes acetaldehyde, but the method is not specific to acetaldehyde analyses. However, because it was inadvertently included for the TO-15 analysis in the ETSA QAPP and so the laboratory reported concentrations from the TO-15 analyses. Those reported concentrations were significantly higher than those obtained using TO-11A, as much as a factor of 30. The minimum-reported concentrations observed using TO-11A were of the order of 0.2 ug/m^3 , while the minimum TO-15 concentrations were of the order of 7 ug/m^3 . Such a discrepancy would indicate either an extremely low bias for TO-11A or an interference effect for TO-15. TtNUS personnel are not aware of any reports of low bias for acetaldehyde using TO-11A. GC/MS analysis quantifies acetaldehyde using a mass to charge ratio ion of 44 atomic mass units (amu). That mass to charge ratio is the same mass to charge ratio as carbon dioxide and there is a high potential for positive interferences that can lead to falsely elevated values. Carbon dioxide is contained within instrument signal background. Method-validation studies and quality parameters specific to acetaldehyde are not available because method TO-15 is not generally used to quantify it. In addition, laboratories do not usually make special efforts to calibrate for acetaldehyde during TO-15 analyses or to correct for interferences.

TtNUS performed a limited comparison study for the analysis of acetaldehyde using TO-11A and TO-15. The study used an acetaldehyde standard at a concentration of approximately 110 parts per billion by volume, following the approach described above for the naphthalene portion of the study. Table 2 presents the results. For both methods, the recoveries are within acceptable ranges. However, the test standard contained only acetaldehyde, which would minimize the possibility of interferences. Because the study could not test for interference effects, the comparison study is inconclusive with regard to evaluating the appropriateness of TO-15 data.

As a part of their quality assurance process, the laboratory has analyzed an acetaldehyde proficiency test sample provided by ERA, using method TO-11A. The recovery of acetaldehyde for method TO-11A was 80%, which is well within the acceptance limits for the method. This provides strong evidence of the validity of the laboratory's application of TO-11A for the acetaldehyde analysis. Because the analysis of the acetaldehyde by TO-15 was unintentional, it was not a component of the proficiency-test sample from ERA and so there is no proficiency result available to evaluate the method.

TtNUS has concluded that assessments of the ambient air should be based on data from the EPA-prescribed method, TO-11A. This is because TO-11A is a validated method specific to the class of compounds of interest. In addition, the possibility of interferences limits the validity of the TO-15 data. Without a sound technical basis, use of a procedure other than the prescribed one is not technically supportable.

Table 1
Naphthalene TO-13A and TO-15 Comparisons

Sample Train	Naphthalene	Method Used	Average Result	Units	Anticipated Result	% of Anticipated (Recovery)

NAPLES Public Health Evaluation

U.S. Navy, Naples Housing Office Premise ID: Parco Artemide

Dear Parco Artemide Resident:

SUBJECT: Phase I Screening Risk Evaluation for Parco Artemide Residences

The Navy Public Health Evaluation Team has completed a Screening Risk Evaluation (SRE) of soil, soil gas and tap water samples that were collected at Parco Artemide residences from 06/27/2008 to 08/05/2008 (See Figure 1). The purpose of the SRE is to evaluate the potential human health risks to Navy personnel and their families residing in the Naples area as a result of public health concerns that could be related to improper refuse disposal (including open burning) and hazardous waste disposal practices. This memo summarizes the results of the investigation that was performed at Parco Artemide residences. These sampling results were compared to U.S. Environmental Protection Agency (USEPA) health standards and of the ten residences sampled in the Parco, nine have been assessed to be Acceptable and one has been assessed to be Unacceptable.

SCREENING RISK EVALUATION RESULTS

The environmental sampling results for soil, soil gas and tap water were compared to risk-based regional screening levels (RSLs) and drinking water standards (maximum contaminant levels [MCLs]) to evaluate potential risks to human health. These levels are considered by the USEPA to be protective of human health. Concentrations of chemicals in soil, soil gas and tap water that exceed these levels may be of concern. Please see Attachment A for further discussion of the SRE approach.

These sampling results are being used as the basis for making recommendations for your residence. They will also be used as part of the overall effort in evaluating potential risks in the Naples area. The two potential outcomes of the SRE are that risks at your residence were: 1) Acceptable or 2) Unacceptable. Please see Attachment B for further discussion of these risk categories. This determination is based on a number of factors and assumes that an individual lives at the residence for 30-years, which is typically used by the USEPA to evaluate residential locations. Your actual risk may be significantly less than the risks presented in this memo. For example, if you live at this location for only three years and do not drink the tap water, then your risks will be significantly less than those presented in this memo.

Finally, risks presented in this SRE are based on a single sampling event at each residence of Parco Artemide. A single sample only provides a "snapshot" of concentrations that are present in soil, soil gas and tap water. One sample may or may not be representative of the soil, soil gas and tap water concentrations present each residence. Please see Attachment C for the sampling results from your residence.

SUBJECT: Phase I Screening Risk Evaluation for Parco Artemide Residences

Typically, in SRE reports, total risks are determined by calculating the potential risk for all of the various ways one might be exposed to contaminants, which are referred to as exposure pathways such as ingestion, inhalation, dermal contact, et cetera. For Naples, Navy leadership has implemented a Bottled Water Advisory and is requiring landlords to provide a water service from Navy-approved sources to eliminate the tap water ingestion exposure pathway. Therefore, we are calculating the risk two ways, assuming exposure via the ingestion pathway, and assuming no exposure via the ingestion pathway. Both of these risk determinations are described below and a table presenting the comparison of the environmental sampling results collected at your residence and applicable screening concentrations is presented in Attachment D.

Risks Calculated Assuming that Tap Water IS Used for Drinking, Cooking, Brushing Teeth and Making Ice

If the tap water at Parco Artemide is used for drinking, cooking, brushing teeth and making ice (in addition to other household uses), then based on USEPA RSLs and MCLs, the risks at eight out of ten residence are Acceptable and two are Unacceptable due to concentrations of chemicals detected in soil and tap water. Of the nearly 220 chemicals that were tested in soil and tap water and the approximately 40 that were tested for in soil gas, three were detected at levels of potential concern¹.

Risks Calculated Assuming that Tap Water IS NOT Used for Drinking, Cooking, Brushing Teeth and Making Ice

The Navy has determined that the tap water in Naples should not be used for drinking, cooking, brushing teeth, or making ice. Therefore, if the tap water at Parco Artemide is not used for drinking, cooking, brushing teeth and making ice (i.e., tap water is only used for other household uses such as showering or washing clothes), then based on USEPA RSLs and MCLs, the risks at nine out of ten residence are Acceptable and one is Unacceptable due to concentrations of chemicals detected in soil and tap water. Of the nearly 220 chemicals that were tested in soil and tap water and approximately 40 that were tested for in soil gas, two were detected at a level of potential concern¹.

Summary of Chemical-Specific Results

In soil, total carcinogenic polycyclic aromatic hydrocarbons (PAHs) exceeded its RSL at location AR03. In tap water, lead exceeded its RSL at locations AR11 and AR16, and naphthalene exceeded its RSL at location AR16. Please see Table 1 for a summary of Parco Artemide residence risks by location.

- 1) PAHs are a class of chemicals which are typically produced during incomplete burning of coal, oil and gas, or other organic substances. They are a product of combustion from common sources such as motor vehicles, wood burning stoves,

¹ This excludes naturally-occurring chemicals, such as arsenic.

SUBJECT: Phase I Screening Risk Evaluation for Parco Artemide Residences

cigarette smoke, industrial smoke or soot, or incomplete burning of wood or materials such as garbage.

- 2) The lead ingestion RSL exceedances are mitigated by the use of bottled water. Lead occurs naturally in the earth's crust. The largest use for inorganic lead is in storage batteries in motor vehicles, although elevated lead in drinking water could be an indication of corrosion of household plumbing systems.
- 3) The naphthalene inhalation RSL exceedance cannot be totally mitigated by bottled water; there will be some exposure via inhalation due to household uses of tap water (e.g., washing clothes and showering). Naphthalene is contained in fuels such as petroleum and coal and is also produced by burning tobacco or wood products. The major commercial use of naphthalene is in the manufacture of polyvinyl chloride (PVC) plastics. It is also found in moth repellents and toilet deodorant blocks.

For more information on these chemicals, please see Attachment E.

It should be noted that the concentrations of naturally-occurring arsenic in soil and tap water were above RSLs at all Parco Artemide residences and the concentrations of naturally-occurring nickel in tap water at locations AR03, AR09 and AR11 were above RSLs.

- 1) Arsenic in soil and tap water is often associated with volcanic activity. This is similar to areas in the United States (e.g., Puget Sound, Washington).
- 2) Nickel is a very abundant natural element that can be combined with other metals, such as iron, copper, chromium and zinc, to form alloys, most commonly stainless steel. These alloys are also used to make coins, jewelry and items such as valves and heat exchangers.

USEPA risk assessors also consider background concentrations of naturally-occurring metals (identified as Inorganics in Attachment D), such as arsenic and nickel, when evaluating risks. The concentrations of these naturally-occurring substances found at your residence were not included in risk-management decisions. The concentrations of metals in soil at your residence were similar to background concentrations found in the Naples area. The concentrations of arsenic and nickel in tap water were below the MCL for all Parco Artemide residences. For more information on arsenic and nickel, please see Attachment E.

The risk-management decision (i.e., Acceptable or Unacceptable) presented in this memo is based on the Incremental Risk (i.e., the risks not including natural background). See the footnotes in Attachment D for more information.

Actions that the Navy Has Taken Based on the Sampling Results

Italian authorities have been and will continue to be notified of the results of the environmental sampling. (Parco Artemide is no longer utilized by the Navy as government quarters.)

SUBJECT: Phase I Screening Risk Evaluation for Parco Artemide Residences

Navy leadership is committed to your health and well-being. The U.S. and Italian governments have both made this study a top priority and we will keep you informed every step of the way. We appreciate your patience with this deliberate and complex process.

We encourage you to ask questions, attend Town Hall Meetings, check the website (<https://www.cnmc.navy.mil/Naples/Programs/HealthAwareness>), and use your chain of command for assistance in getting the answers you deserve. We have established an Environmental Health Information Office as a resource to help with your health related questions or concerns, which is located on the ground floor of Naval Hospital Naples, Room 1096, DSN 629-6071. CDR Tim Halenkamp, who runs this office, is also the Director of Occupational and Environmental Medicine and can be reached at DSN 314-626-6807 or Commercial 39-081-568-6807.

Attachment A

Overview of the Phase I Screening Risk Evaluation Approach

Comparison of Environmental Sampling Results to Risk-Based Screening Concentrations

To determine whether or not the sampling results for soil, soil gas, and tap water are potentially of concern to human health, the sampling results were compared to United States Environmental Protection Agency (USEPA) risk-based regional screening levels (RSLs). The RSLs incorporate many conservative assumptions about exposure to be protective of human health.

Concentrations for each chemical were compared to:

1. USEPA RSLs based on 30-year residential exposure
2. USEPA Maximum Contaminant Levels (MCLs) for Drinking Water

The USEPA RSLs are calculated based on carcinogenic (i.e., cancer) risks and noncarcinogenic (i.e., noncancer) health effects. Cancer risk is an estimate of how exposure to a chemical may increase the normal or expected rate of developing cancer in a population of people. The USEPA generally evaluates cancer risk¹ as follows:

- **Acceptable Risk** – A cancer risk of 1×10^{-6} (i.e., one person out of 1,000,000 will develop cancer) or less is considered safe (i.e., acceptable). Note: The USEPA generally also considers the range between one in 10,000 (1×10^{-4}) and one in 1,000,000 (1×10^{-6}) people as a safe (i.e., acceptable) range, and actions to reduce the risk may or may not be required based on various site-specific factors. The USEPA typically considers additional actions to reduce cancer risks that are close to or greater than one in 10,000 (1×10^{-4}) people.
- **Unacceptable Risk** – USEPA considers an increase of “more than” one additional case of cancer (or greater) in 10,000 (1×10^{-4}) people to be of concern (i.e., unacceptable).

Noncancer health effects are expressed by a number known as the “hazard quotient” or “HQ.” The HQ compares the amount of a chemical that people may have been exposed to over a specified time period with the amount that is considered to have no effect (i.e., safe). If people are exposed to an amount greater than that considered safe for a particular chemical, then the ratio will be greater than one. Because people can be

¹ For the purposes of the Phase I SRE, the Navy has decided to use only two categories to categorize risks (i.e., “Acceptable” or “Unacceptable”). See Appendix B for the definition of *Acceptable* and *Unacceptable* risks).

exposed to more than one chemical at a time, the HQs for different chemicals are added together to give an overall “Hazard Index” or “HI,” unless data is available to indicate that they should not be added together. USEPA policy considers chemical concentrations resulting in an HI above one to be of concern for developing potential noncancer health effects. Professional judgment must be used to evaluate the potential noncancer health effects related to the concentration of these chemicals to determine if actions to reduce the risk are needed.

Comparison of Environmental Sampling Results to Maximum Contaminant Levels (MCLs)

MCLs are maximum permissible levels of a contaminant in public water supplies. For private water supplies, MCLs are useful for determining potability. MCLs are protective of public health during a lifetime (70 years) for an individual who drinks two liters of water per day.

Attachment B

Risk Management Criteria

This Screening Risk Evaluation (SRE) characterizes the potential health risks associated with living at your residence for 30 years. This is generally a conservative assumption because typical tour lengths range from three to six years. The risk evaluation results were placed into one of two categories: 1) Acceptable Risks or 2) Unacceptable Risks. Based on the results of the SRE, the appropriate course of action will be taken to ensure the safety of U.S. Navy military and civilian personnel and their families. The criteria for each of the risk-management categories are defined below.

**United States Navy
Naples, Italy Phase I Screening Risk Evaluation
Risk Management Categories**

Criteria/ Actions	Acceptable Risks	Unacceptable Risks
Risk Criteria – for Residences Using Tap Water for Drinking, Cooking, Brushing Teeth, and Making Ice⁶	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). Applies to all chemicals. 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). Applies to all chemicals.
Risk Criteria – for Residences <u>NOT</u> Using Tap Water for Drinking, Cooking, Brushing Teeth, and Making Ice⁷	<ul style="list-style-type: none"> • Total NCEF less than or equal to 1; and • Total CEF less than or equal to 10; and • Concentration less than or equal to USEPA MCL (tap water). Applies only to Fecal Coliform and Total Coliforms (including Fecal Coliform and E. Coli). 	<ul style="list-style-type: none"> • Total NCEF greater than 1; or • Total CEF greater than 10; or • Concentration greater than the USEPA MCL (tap water). Applies only to Fecal Coliform and Total Coliforms (including Fecal Coliform and E. Coli).

**United States Navy
Naples, Italy Phase I Screening Risk Evaluation
Risk Management Categories**

Criteria/ Actions	Acceptable Risks	Unacceptable Risks
	<p>Notes:</p> <ol style="list-style-type: none"> 1. Noncancer exceedance factors (NCEFs) were calculated by dividing the maximum detected concentrations by noncancer-based U.S. Environmental Protection Agency (USEPA) Regional Screening Levels (RSLs). 2. Cancer exceedance factors (CEFs) were calculated by dividing the maximum detected concentrations by cancer-based USEPA RSLs. 3. The individual NCEFs and CEFs were summed to provide the total NCEF and total CEF. 4. An NCEF of 1 corresponds to a Hazard Index of 1. 5. A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million). A CEF of 10 corresponds to a cancer risk of 1×10^{-5} (one in a one hundred thousand). 6. The tap water RSLs used to evaluate residences that <u>USE</u> tap water for drinking, cooking, brushing teeth, and making ice were based on ingestion and inhalation of household uses (e.g., showering) of tap water. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate. 7. The tap water RSLs used to evaluate residences that <u>DO NOT</u> use tap water for drinking, cooking, brushing teeth, and making ice were based on inhalation of household uses (e.g., showering) of tap water only. This evaluation also included RSLs for evaluating soil and soil gas, as appropriate.

-- = The chemical was not analyzed or no value was available.

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E.Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Data Qualifiers:

Blank (i.e., no qualifier) = The chemical was detected.

> = The chemical was detected.

J = The chemical was detected but the concentration reported is an estimated value.

U = The chemical was not detected.

< = The chemical was not detected.

-- = The chemical was not analyzed or no value was available.

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E.Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Data Qualifiers:

Blank (i.e., no qualifier) = The chemical was detected.

> = The chemical was detected.

J = The chemical was detected but the concentration reported is an estimated value.

U = The chemical was not detected.

< = The chemical was not detected.

-- = The chemical was not analyzed or no value was available.

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E.Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Data Qualifiers:

Blank (i.e., no qualifier) = The chemical was detected.

> = The chemical was detected.

J = The chemical was detected but the concentration reported is an estimated value.

U = The chemical was not detected.

< = The chemical was not detected.

INCREMENTAL RISK					0.03	2.0

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

			INCREMENTAL RISK	0	0

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

INCREMENTAL RISK				0	0

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

			INCREMENTAL RISK		0.04	0.1

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

TOTAL RISK					2.2	36.9
BACKGROUND RISK					2.2	36.7
INCREMENTAL RISK					0.05	0.3

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

Naples, Italy Background (Maximum) = Cicchella, Domencio, et al. *Background and baseline concentration values of elements harmful to human health in the volcanic soils of the metropolitan and provincial areas of Napoli (Italy)*.

Geochemistry: Exploration, Environment, Analysis Vol. 5 2005, pp.29-40.

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are present at concentrations less than or equal to the Naples, Italy Background (Maximum) concentrations.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL.

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = None of the volatile organic chemicals tested for in the soil gas samples are naturally occurring. Therefore, the background risk is zero.

Incremental Risk = The Total Risk. The risk management category for this location (i.e., Acceptable or Unacceptable) is based on this risk.

-- = The chemical was not analyzed, not detected or no value was available.

CEF = Cancer exceedance factor. CEFs were calculated by dividing detected concentrations by cancer-based USEPA RSLs.

A CEF of 1 corresponds to a cancer risk of 1×10^{-6} (one in a million).

NCEF = Noncancer exceedance factor. NCEFs were calculated by dividing detected concentrations by noncancer-based USEPA RSLs.

An NCEF of 1 corresponds to a Hazard Index of 1.

RSL = Regional Screening Level

USEPA = United States Environmental Protection Agency

USEPA MCL EF = USEPA Maximum Contaminant Level Exceedance Factor. USEPA MCL EFs were calculated by dividing detected concentrations by the USEPA MCLs.

USEPA MCL = USEPA Maximum Contaminant Levels (<http://www.epa.gov/ogwdw/contaminants/index.html>).

Fecal Coliform, Fecal Steptococcus and Total Coliforms (including Fecal Coliform and E. Coli) are reported in CFU/100 mL (CFU = colony forming units).

Heterotrophic Plate Count is reported in CFU/1 mL.

Risk calculations may appear to not add correctly due to rounding.

Total Risk = The risk for all chemicals.

Background Risk = The risk for chemicals (i.e., inorganic elements) that are naturally occurring in the environment but does not include lead, copper and thallium.

Incremental Risk = The risk for chemicals that are not naturally occurring in the environment. The risk management category for this location

(i.e., Acceptable or Unacceptable) is based on this risk. This includes lead, copper and thallium.

The ingestion exceedance factors are presented for informational purposes only. The risk-management decision (i.e., Acceptable or Unacceptable) will be made

based on inhalation because the Navy leadership has stated that all personnel should be using bottled water for drinking, cooking, and brushing teeth.

Attachment E
Chemical Fact Sheets

**This page has been left blank intentionally
to allow for double-sided printing.**

This fact sheet answers the most frequently asked health questions (FAQs) about arsenic. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to higher than average levels of arsenic occur mostly in the workplace, near hazardous waste sites, or in areas with high natural levels. At high levels, inorganic arsenic can cause death. Exposure to lower levels for a long time can cause a discoloration of the skin and the appearance of small corns or warts. Arsenic has been found in at least 1,149 of the 1,684 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is arsenic?

Arsenic is a naturally occurring element widely distributed in the earth's crust. In the environment, arsenic is combined with oxygen, chlorine, and sulfur to form inorganic arsenic compounds. Arsenic in animals and plants combines with carbon and hydrogen to form organic arsenic compounds.

Inorganic arsenic compounds are mainly used to preserve wood. Copper chromated arsenate (CCA) is used to make "pressure-treated" lumber. CCA is no longer used in the U.S. for residential uses; it is still used in industrial applications. Organic arsenic compounds are used as pesticides, primarily on cotton fields and orchards.

What happens to arsenic when it enters the environment?

- Arsenic occurs naturally in soil and minerals and may enter the air, water, and land from wind-blown dust and may get into water from runoff and leaching.
- Arsenic cannot be destroyed in the environment. It can only change its form.
- Rain and snow remove arsenic dust particles from the air.
- Many common arsenic compounds can dissolve in water. Most of the arsenic in water will ultimately end up in soil or sediment.
- Fish and shellfish can accumulate arsenic; most of this arsenic is in an organic form called arsenobetaine that is much less harmful.

How might I be exposed to arsenic?

- Ingesting small amounts present in your food and water or breathing air containing arsenic.
- Breathing sawdust or burning smoke from wood treated with arsenic.
- Living in areas with unusually high natural levels of arsenic in rock.
- Working in a job that involves arsenic production or use, such as copper or lead smelting, wood treating, or pesticide application.

How can arsenic affect my health?

Breathing high levels of inorganic arsenic can give you a sore throat or irritated lungs.

Ingesting very high levels of arsenic can result in death. Exposure to lower levels can cause nausea and vomiting, decreased production of red and white blood cells, abnormal heart rhythm, damage to blood vessels, and a sensation of "pins and needles" in hands and feet.

Ingesting or breathing low levels of inorganic arsenic for a long time can cause a darkening of the skin and the appearance of small "corns" or "warts" on the palms, soles, and torso.

Skin contact with inorganic arsenic may cause redness and swelling.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

Almost nothing is known regarding health effects of organic arsenic compounds in humans. Studies in animals show that some simple organic arsenic compounds are less toxic than inorganic forms. Ingestion of methyl and dimethyl compounds can cause diarrhea and damage to the kidneys

How likely is arsenic to cause cancer?

Several studies have shown that ingestion of inorganic arsenic can increase the risk of skin cancer and cancer in the liver, bladder, and lungs. Inhalation of inorganic arsenic can cause increased risk of lung cancer. The Department of Health and Human Services (DHHS) and the EPA have determined that inorganic arsenic is a known human carcinogen. The International Agency for Research on Cancer (IARC) has determined that inorganic arsenic is carcinogenic to humans.

How can arsenic affect children?

There is some evidence that long-term exposure to arsenic in children may result in lower IQ scores. There is also some evidence that exposure to arsenic in the womb and early childhood may increase mortality in young adults.

There is some evidence that inhaled or ingested arsenic can injure pregnant women or their unborn babies, although the studies are not definitive. Studies in animals show that large doses of arsenic that cause illness in pregnant females, can also cause low birth weight, fetal malformations, and even fetal death. Arsenic can cross the placenta and has been found in fetal tissues. Arsenic is found at low levels in breast milk.

How can families reduce the risks of exposure to arsenic?

If you use arsenic-treated wood in home projects, you should wear dust masks, gloves, and protective clothing to decrease exposure to sawdust.

- If you live in an area with high levels of arsenic in water or soil, you should use cleaner sources of water and limit contact with soil.
- If you work in a job that may expose you to arsenic, be aware that you may carry arsenic home on your clothing, skin, hair, or tools. Be sure to shower and change clothes before going home.

Is there a medical test to determine whether I've been exposed to arsenic?

There are tests available to measure arsenic in your blood, urine, hair, and fingernails. The urine test is the most reliable test for arsenic exposure within the last few days. Tests on hair and fingernails can measure exposure to high levels of arsenic over the past 6-12 months. These tests can determine if you have been exposed to above-average levels of arsenic. They cannot predict whether the arsenic levels in your body will affect your health.

Has the federal government made recommendations to protect human health?

The EPA has set limits on the amount of arsenic that industrial sources can release to the environment and has restricted or cancelled many of the uses of arsenic in pesticides. EPA has set a limit of 0.01 parts per million (ppm) for arsenic in drinking water.

The Occupational Safety and Health Administration (OSHA) has set a permissible exposure limit (PEL) of 10 micrograms of arsenic per cubic meter of workplace air (10 µg/m³) for 8 hour shifts and 40 hour work weeks.

Where can I get more information? For more information, contact the Agency for Toxic Substances and Disease Registry, Division of Toxicology and Environmental Medicine, 1600 Clifton Road NE, Mailstop F-32, Atlanta, GA 30333. Phone: 1-800-232-4636, FAX: 770-488-4178. ToxFAQs Internet address via WWW is <http://www.atsdr.cdc.gov/toxfaq.html>. ATSDR can tell you where to find occupational and environmental health clinics. Their specialists can recognize, evaluate, and treat illnesses resulting from exposure to hazardous substances. You can also contact your community or state health or environmental quality department if you have any more questions or concerns.

This fact sheet answers the most frequently asked health questions (FAQs) about lead. For more information, call the ATSDR Information Center at 1-800-232-4636. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to lead can happen from breathing workplace air or dust, eating contaminated foods, or drinking contaminated water. Children can be exposed from eating lead-based paint chips or playing in contaminated soil. Lead can damage the nervous system, kidneys, and reproductive system. Lead has been found in at least 1,272 of the 1,684 National Priority List sites identified by the Environmental Protection Agency (EPA).

What is lead?

Lead is a naturally occurring bluish-gray metal found in small amounts in the earth's crust. Lead can be found in all parts of our environment. Much of it comes from human activities including burning fossil fuels, mining, and manufacturing.
